9.3.12 PMECTRLSTATUS - PME Control and Status Register (PMECTRLSTATUS)—Offset 84h

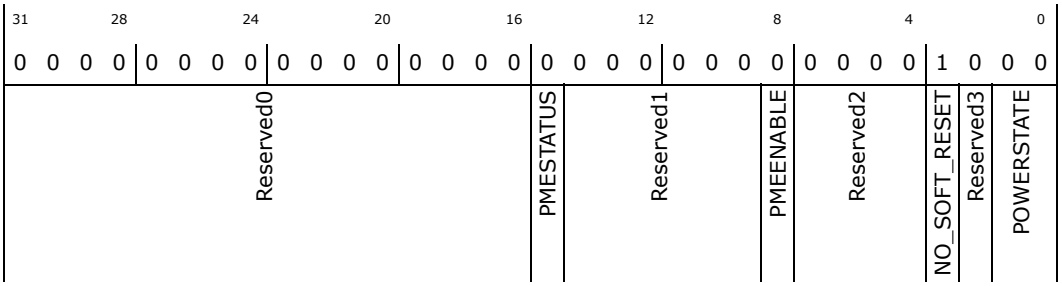
PMECTRLSTATUS - PME Control and Status Register

Access Method

Type: PCI Configuration Register (Size: 32 bits)

Offset: [B:0, D:24, F:0] + 84h

Default: 00000008h



Bit Range	Default & Access	Field Name (ID): Description
31:16	0x0 RO	**Reserved0:** Reserved
15	0x0 RW/1C	**PMESTATUS:** PME Status: 0 = Software clears the bit by writing a 1 to it. 1 = This bit is set when the AHB Device would normally assert the PME# signal independent of the state of the PME Enable bit (bit 8 in this register)
14:9	0x0 RO	**Reserved1:** Reserved
8	0x0 RW	**PMEENABLE:** PME Enable: A 1 enables the function to assert PME#. When 0, PME# message on SB is disabled.
7:4	0x0 RO	**Reserved2:** Reserved
3	0x1 RO	**NO_SOFT_RESET:** No_Soft_Reset: This bit indicates that devices transitioning from D3hot to D0 because of PowerState commands do not perform an internal reset. Configuration Context is preserved.
2	0x0 RO	**Reserved3:** Reserved
1:0	0x0 RW	**POWERSTATE:** Power State : This field is used both to determine the current power state of the AHB IP and to set a new power state. The values are: 00 = D0 state 11 = D3HOT state Others = Reserved Notes: If software attempts to write a value of 01b or 10b in to this field, the write operation must complete normally; however, the data is discarded and no state change occurs. When in the D3HOT states, interrupts are blocked. D3Hot will not be used for Downstream decode on fabric ports.

9.6.3 SSP Status Register (SSSR)—Offset 8h

The Enhanced SSP Status registers contain bits that signal overrun errors as well as the Transmit and Receive FIFO service requests. Each of these hardware-detected events signals an Interrupt request to the Interrupt controller. The Status register also contains flags that indicate when the Enhanced SSP is actively transmitting data, when the Transmit FIFO is not full, and when the Receive FIFO is not empty. One Interrupt signal is sent to the Interrupt Controller for each SSP. These events can cause an Interrupt: End-of-Chain, Receiver Time-out, Peripheral Trailing Byte, Receive FIFO overrun, Receive FIFO request, and Transmit FIFO request.

9.6.4 SSP Interrupt Test Register (SSITR)—Offset Ch

The read-write SSP Interrupt Test registers should be used only for testing purposes. Writing a 1 to the test transmit FIFO request SSITR.TTFS, bit 5, will generate a non-maskable Interrupt strobe signal to the Interrupt controller, and a DMA request for the Transmit FIFO. Writing a 1 to the test receive FIFO request SSITR.TRFS, bit 6, will generate a non-maskable Interrupt strobe signal to the Interrupt controller, and a DMA request for the Receive FIFO. Writing a 1 to the test receive FIFO overrun bit SSITR.TROR, bit 7, will generate a non-maskable Interrupt strobe signal to the Interrupt controller only, no DMA request will be made. Setting any of these bits will also cause the corresponding status bit(s) to be set in the Enhanced SSP Status register (SSSR). The Interrupt and/or service request, caused by the setting of one of these test bits, will remain active until the test bit is cleared by writing a 0 it. Note that Writes to reserved bits must be zeroes, and Read value of these bits are undetermined.

9.6.5 SSP Data (SSDR)—Offset 10h

The Enhanced SSP Data registers are single address locations that Read-Write data transfers can access. The SSDR represents two physical registers: the first is temporary storage for data on its way out through the Transmit FIFO, the other is temporary storage for data coming in through the Receive FIFO. As the system accesses the register, FIFO Control logic transfers data automatically between register and FIFO as fast as the system moves it. Data in the FIFO shifts up or down to accommodate the new word (unless it's an attempted Write to a full Transmit FIFO). Status bits (such as SSSR.TFL, SSSR.RFL, SSSR.RNE, and SSSR.TNF) show users whether the FIFO is full, above/below a programmable FIFO trigger threshold, or empty. For Transmit data transfers (Write from system to SSP peripheral), the register can be loaded (written) by the system processor anytime it falls below its threshold level when using programmed I/O. When a data size of less than 32-bits is selected, users should not left-justify data written to the Transmit FIFO. Transmit logic left-justifies the data and ignores any unused bits. Received data of less than 32-bits is automatically right-justified in the Receive FIFO. When the Enhanced SSP is programmed for National Semiconductor Microwire* frame format and if the size for Transmit data is 8-bits as selected by SSCR1.MWDS=0, then the most significant 24-bits are ignored. Similarly, if the size for the Transmit data is 16-bit as selected by SSCR1.MWDS=1, then most significant 16-bits are ignored. The SSCR0.DSS field controls the Receive data size.

9.6.11 SSP Audio Clock Divider (SSACD)—Offset 3Ch

The Enhanced SSP Audio Clock Divider registers are read-write registers that indicate which clock frequency is sent to the Enhanced SSP and to the SYSCLK pin. If SSCR0.SCR is not 0, then there is no guaranteed phase relationship between SYSCLK and SSPSCLK. The SSPSFRM Frame Synch Sampling Frequency is calculated by dividing the chosen PLL output clock frequency (SSACD.ACPS) by the chosen divider (SSACD.ACDS) which gives the SYSCLK frequency. The SYSCLK is then divided by 4 (or by 1) to get the SSPSCLK. The SSPSCLK is divided by the data size (EDSS, DSS values)

and by the number of time slots being used (SSCR0.FRDC value), if any, to give the SSPSFRM frequency. Note that Writes to reserved bits must be zeroes, and Read value of these bits are undetermined.

9.8.3 SSP Status Register (SSSR)—Offset 8h

The Enhanced SSP Status registers contain bits that signal overrun errors as well as the Transmit and Receive FIFO service requests. Each of these hardware-detected events signals an Interrupt request to the Interrupt controller. The Status register also contains flags that indicate when the Enhanced SSP is actively transmitting data, when the Transmit FIFO is not full, and when the Receive FIFO is not empty. One Interrupt signal is sent to the Interrupt Controller for each SSP. These events can cause an Interrupt: End-of-Chain, Receiver Time-out, Peripheral Trailing Byte, Receive FIFO overrun, Receive FIFO request, and Transmit FIFO request.

9.8.4 SSP Interrupt Test Register (SSITR)—Offset Ch

The read-write SSP Interrupt Test registers should be used only for testing purposes. Writing a 1 to the test transmit FIFO request SSITR.TTFS, bit 5, will generate a non-maskable Interrupt strobe signal to the Interrupt controller, and a DMA request for the Transmit FIFO. Writing a 1 to the test receive FIFO request SSITR.TRFS, bit 6, will generate a non-maskable Interrupt strobe signal to the Interrupt controller, and a DMA request for the Receive FIFO. Writing a 1 to the test receive FIFO overrun bit SSITR.TROR, bit 7, will generate a non-maskable Interrupt strobe signal to the Interrupt controller only, no DMA request will be made. Setting any of these bits will also cause the corresponding status bit(s) to be set in the Enhanced SSP Status register (SSSR). The Interrupt and/or service request, caused by the setting of one of these test bits, will remain active until the test bit is cleared by writing a 0 it. Note that Writes to reserved bits must be zeroes, and Read value of these bits are undetermined.

9.8.5 SSP Data (SSDR)—Offset 10h

The Enhanced SSP Data registers are single address locations that Read-Write data transfers can access. The SSDR represents two physical registers: the first is temporary storage for data on its way out through the Transmit FIFO, the other is temporary storage for data coming in through the Receive FIFO. As the system accesses the register, FIFO Control logic transfers data automatically between register and FIFO as fast as the system moves it. Data in the FIFO shifts up or down to accommodate the new word (unless it's an attempted Write to a full Transmit FIFO). Status bits (such as SSSR.TFL, SSSR.RFL, SSSR.RNE, and SSSR.TNF) show users whether the FIFO is full, above/below a programmable FIFO trigger threshold, or empty. For Transmit data transfers (Write from system to SSP peripheral), the register can be loaded (written) by the system processor anytime it falls below its threshold level when using programmed I/O. When a data size of less than 32-bits is selected, users should not left-justify data written to the Transmit FIFO. Transmit logic left-justifies the data and ignores any unused bits. Received data of less than 32-bits is automatically right-justified in the Receive FIFO. When the Enhanced SSP is programmed for National Semiconductor Microwire* frame format and if the size for Transmit data is 8-bits as selected by SSCR1.MWDS=0, then the most significant 24-bits are ignored. Similarly, if the size for the Transmit data is 16-bit as selected by SSCR1.MWDS=1, then most significant 16-bits are ignored. The SSCR0.DSS field controls the Receive data size.

9.8.11 SSP Audio Clock Divider (SSACD)—Offset 3Ch

The Enhanced SSP Audio Clock Divider registers are read-write registers that indicate which clock frequency is sent to the Enhanced SSP and to the SYSCLK pin. If SSCR0.SCR is not 0, then there is no guaranteed phase relationship between SYSCLK and SSPSCLK. The SSPSFRM Frame Synch Sampling Frequency is calculated by dividing the chosen PLL output clock frequency (SSACD.ACPS) by the chosen divider (SSACD.ACDS) which gives the SYSCLK frequency. The SYSCLK is then divided by 4 (or by 1) to get the SSPSCLK. The SSPSCLK is divided by the data size (EDSS, DSS values)

and by the number of time slots being used (SSCR0.FRDC value), if any, to give the SSPSFRM frequency. Note that Writes to reserved bits must be zeroes, and Read value of these bits are undetermined.

9.10.3 SSP Status Register (SSSR)—Offset 8h

The Enhanced SSP Status registers contain bits that signal overrun errors as well as the Transmit and Receive FIFO service requests. Each of these hardware-detected events signals an Interrupt request to the Interrupt controller. The Status register also contains flags that indicate when the Enhanced SSP is actively transmitting data, when the Transmit FIFO is not full, and when the Receive FIFO is not empty. One Interrupt signal is sent to the Interrupt Controller for each SSP. These events can cause an Interrupt: End-of-Chain, Receiver Time-out, Peripheral Trailing Byte, Receive FIFO overrun, Receive FIFO request, and Transmit FIFO request.

9.10.4 SSP Interrupt Test Register (SSITR)—Offset Ch

The read-write SSP Interrupt Test registers should be used only for testing purposes. Writing a 1 to the test transmit FIFO request SSITR.TTFS, bit 5, will generate a non-maskable Interrupt strobe signal to the Interrupt controller, and a DMA request for the Transmit FIFO. Writing a 1 to the test receive FIFO request SSITR.TRFS, bit 6, will generate a non-maskable Interrupt strobe signal to the Interrupt controller, and a DMA request for the Receive FIFO. Writing a 1 to the test receive FIFO overrun bit SSITR.TROR, bit 7, will generate a non-maskable Interrupt strobe signal to the Interrupt controller only, no DMA request will be made. Setting any of these bits will also cause the corresponding status bit(s) to be set in the Enhanced SSP Status register (SSSR). The Interrupt and/or service request, caused by the setting of one of these test bits, will remain active until the test bit is cleared by writing a 0 it. Note that Writes to reserved bits must be zeroes, and Read value of these bits are undetermined.

9.10.5 SSP Data (SSDR)—Offset 10h

The Enhanced SSP Data registers are single address locations that Read-Write data transfers can access. The SSDR represents two physical registers: the first is temporary storage for data on its way out through the Transmit FIFO, the other is temporary storage for data coming in through the Receive FIFO. As the system accesses the register, FIFO Control logic transfers data automatically between register and FIFO as fast as the system moves it. Data in the FIFO shifts up or down to accommodate the new word (unless it's an attempted Write to a full Transmit FIFO). Status bits (such as SSSR.TFL, SSSR.RFL, SSSR.RNE, and SSSR.TNF) show users whether the FIFO is full, above/below a programmable FIFO trigger threshold, or empty. For Transmit data transfers (Write from system to SSP peripheral), the register can be loaded (written) by the system processor anytime it falls below its threshold level when using programmed I/O. When a data size of less than 32-bits is selected, users should not left-justify data written to the Transmit FIFO. Transmit logic left-justifies the data and ignores any unused bits. Received data of less than 32-bits is automatically right-justified in the Receive FIFO. When the Enhanced SSP is programmed for National Semiconductor Microwire* frame format and if the size for Transmit data is 8-bits as selected by SSCR1.MWDS=0, then the most significant 24-bits are ignored. Similarly, if the size for the Transmit data is 16-bit as selected by SSCR1.MWDS=1, then most significant 16-bits are ignored. The SSCR0.DSS field controls the Receive data size.

9.10.11 SSP Audio Clock Divider (SSACD)—Offset 3Ch

The Enhanced SSP Audio Clock Divider registers are read-write registers that indicate which clock frequency is sent to the Enhanced SSP and to the SYSCLK pin. If SSCR0.SCR is not 0, then there is no guaranteed phase relationship between SYSCLK and SSPSCLK. The SSPSFRM Frame Synch Sampling Frequency is calculated by dividing the chosen PLL output clock frequency (SSACD.ACPS) by the chosen divider (SSACD.ACDS) which gives the SYSCLK frequency. The SYSCLK is then divided by 4 (or by 1) to get the SSPSCLK. The SSPSCLK is divided by the data size (EDSS, DSS values)

and by the number of time slots being used (SSCR0.FRDC value), if any, to give the SSPSFRM frequency. Note that Writes to reserved bits must be zeroes, and Read value of these bits are undetermined.

9.12.1 I2C Control Register (IC_CON)—Offset 0h

I2C Control Register

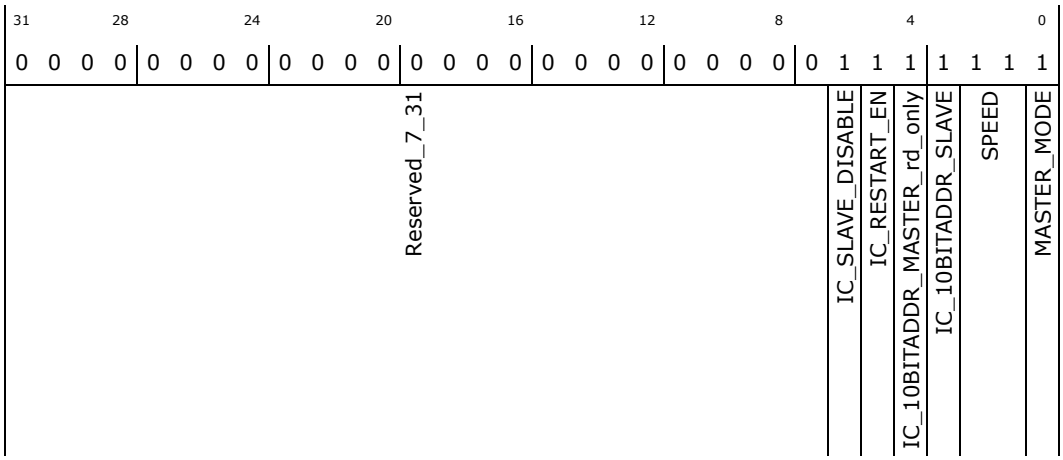
Access Method

Type: Memory Mapped I/O Register (Size: 32 bits)

Offset: [BAR] + 0h

BAR Type: PCI Configuration Register (Size: 32 bits)
BAR Reference: [B:0, D:24, F:1] + 10h

Default: 0000007Fh



Bit Range	Default & Access	Field Name (ID): Description
31:7	0x0 RW	**Reserved_7_31:** Reserved
6	0x1 RW	**IC_SLAVE_DISABLE:** This bit controls whether I2C has its slave disabled. By default, the slave is always enabled (in reset state as well). If you need to disable it after reset, set this bit to 1. If this bit is set (slave is disabled), DW_apb_i2c functions only as a master and does not perform any action that requires a slave.
5	0x1 RW	**IC_RESTART_EN:** Determines whether RESTART conditions may be sent when acting as a master.When the RESTART is disabled, the DW_apb_i2c master is incapable of performing the following functions: Sending a START BYTE. Performing any high-speed mode operation. Performing direction changes in combined format mode. Performing a read operation with a 10-bit address
4	0x1 RO	**IC_10BITADDR_MASTER (IC_10BITADDR_MASTER_rd_only):** controls whether the DW_apb_i2c starts its transfers in 7- or 10-bit addressing mode when acting as a master. If I2C_DYNAMIC_TAR_UPDATE = 1, then this bit is read-only copy of bit 12 of IC_TAR register
3	0x1 RW	**IC_10BITADDR_SLAVE:** When acting as a slave, this bit controls whether the DW_apb_i2c responds to 7- or 10-bit addresses.

Bit Range	Default & Access	Field Name (ID): Description
2:1	0x3 RW	**SPEED:** These bits control at which speed the DW_apb_i2c operates; its setting is relevant only if one is operating the DW_apb_i2c in master mode. Hardware protects against illegal values being programmed by software. This register should be programmed only with a value in the range of 1 to IC_MAX_SPEED_MODE; otherwise, hardware updates this register with the value of IC_MAX_SPEED_MODE.
0	0x1 RW	**MASTER_MODE:** This bit controls whether the DW_apb_i2c master is enabled. Software should ensure that if this bit is set to X, then bit 6 should also be set to X.

9.12.2 I2C Target Address Register (IC_TAR)—Offset 4h

I2C Target Address Register

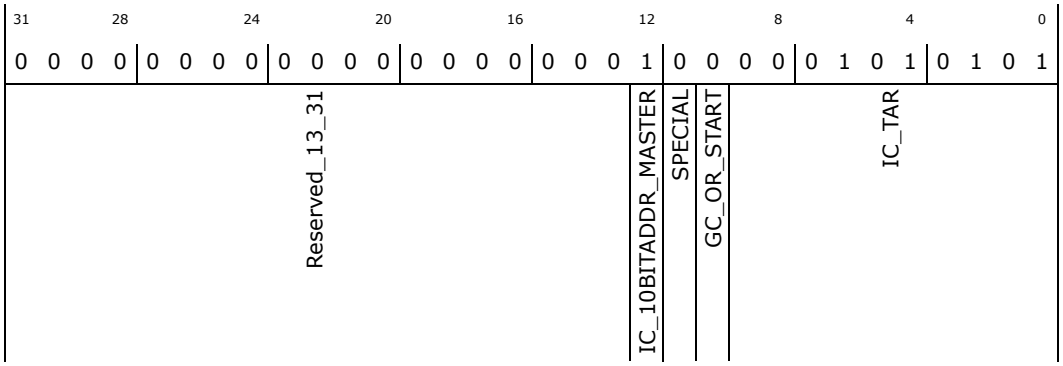
Access Method

Type: Memory Mapped I/O Register (Size: 32 bits)

Offset: [BAR] + 4h

BAR Type: PCI Configuration Register (Size: 32 bits)
BAR Reference: [B:0, D:24, F:1] + 10h

Default: 00001055h



Bit Range	Default & Access	Field Name (ID): Description
31:13	0x0 RW	**Reserved_13_31:** Reserved
12	0x1 RW	**IC_10BITADDR_MASTER:** This bit controls whether the DW_apb_i2c starts its transfers in 7-or 10-bit addressing mode when acting as a master. This bit exists in this register only if the I2C_DYNAMIC_TAR_UPDATE configuration parameter is set to 1
11	0x0 RW	**SPECIAL:** This bit indicates whether software performs a General Call or START BYTE command. 0: ignore bit 10 GC_OR_START and use IC_TAR normally. 1: perform special I2C command as specified in GC_OR_START bit
10	0x0 RW	**GC_OR_START:** If bit 11 (SPECIAL) is set to 1, then this bit indicates whether a General Call(0) or START(1) byte command is to be performed by the DW_apb_i2c.

Bit Range	Default & Access	Field Name (ID): Description
9:0	0x55 RW	**IC_TAR:** This is the target address for any master transaction. When transmitting a General Call, these bits are ignored. To generate a START BYTE, the CPU needs to write only once into these bits.

9.12.3 I2C Slave Address Register (IC_SAR)—Offset 8h

I2C Slave Address Register

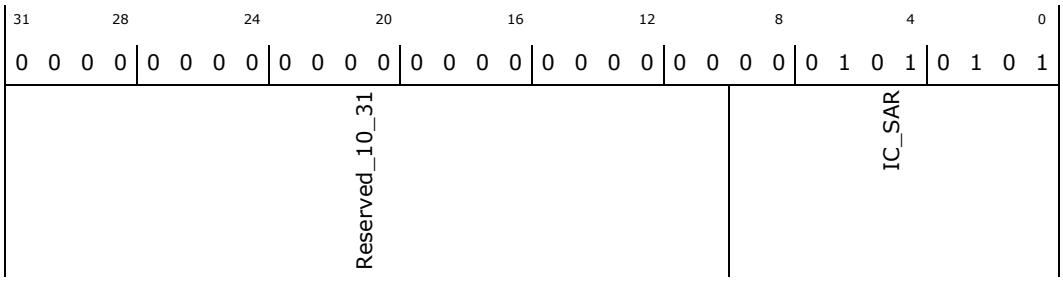
Access Method

Type: Memory Mapped I/O Register (Size: 32 bits)

Offset: [BAR] + 8h

BAR Type: PCI Configuration Register (Size: 32 bits)
BAR Reference: [B:0, D:24, F:1] + 10h

Default: 00000055h



Bit Range	Default & Access	Field Name (ID): Description
31:10	0x0 RW	**Reserved_10_31:** Reserved
9:0	0x55 RW	**IC_SAR:** The IC_SAR holds the slave address when the I2C is operating as a slave. For 7-bit addressing, only IC_SAR[6:0] is used. This register can be written only when the I2C interface is disabled, which corresponds to the IC_ENABLE register being set to 0. Writes at other times have no effect.

9.12.4 I2C High Speed Master Mode Code Address Register (IC_HS_MADDR)—Offset Ch

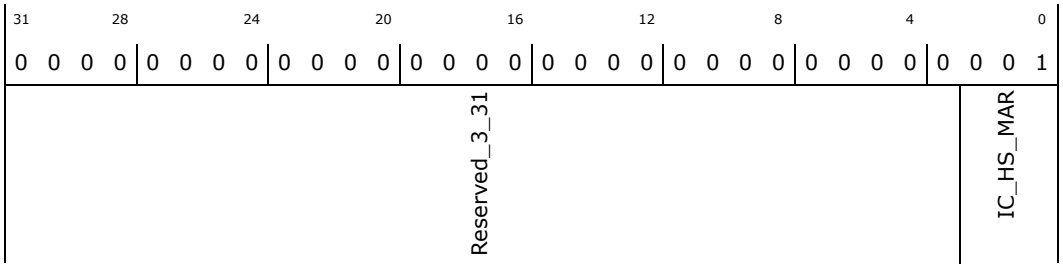
BAR Type: PCI Configuration Register (Size: 32 bits)
BAR Reference: [B:0, D:24, F:1] + 10h

Default: 00000001h



Bit Range	Default & Access	Field Name (ID): Description
31:3	0x0 RW	**Reserved_3_31:** Reserved
2:0	0x1 RW	**IC_HS_MAR:** This bit field holds the value of the I2C HS mode master code. HS-mode master codes are reserved 8-bit codes (00001xxx) that are not used for slave addressing or other purposes. Each master has its unique master code; up to eight highspeed mode masters can be present on the same I2C bus system. Valid values are from 0 to 7. This register goes away and becomes read-only returning 0s if the IC_MAX_SPEED_MODE configuration parameter is set to either Standard (1) or Fast (2). This register can be written only when the I2C interface is disabled, which corresponds to the IC_ENABLE register being set to 0. Writes at other times have no effect.

9.12.5 I2C Rx/Tx Data Buffer and Command Register (IC_DATA_CMD)—Offset 10h

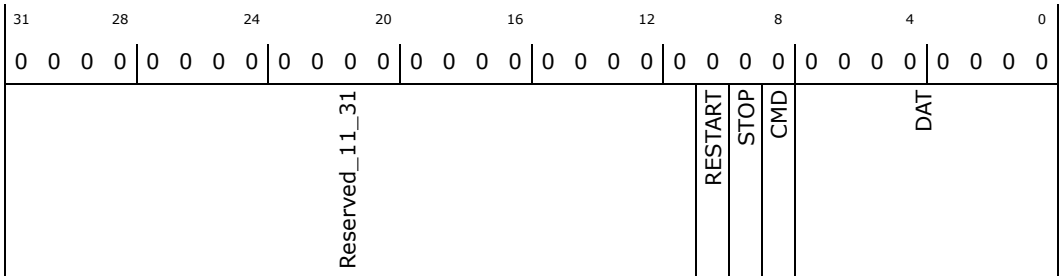
BAR Type: PCI Configuration Register (Size: 32 bits)
BAR Reference: [B:0, D:24, F:1] + 10h

Default: 00000000h



Bit Range	Default & Access	Field Name (ID): Description

10	0x0 RW	**RESTART:** RESTART
9	0x0 RW	**STOP:** STOP
8	0x0 RW	**CMD:** This bit controls whether a read or a write is performed. This bit does not control the direction when the DW_apb_i2c acts as a slave. It controls only the direction when it acts as a master. 1 = Read. 0 = Write
7:0	0x0 RW	**DAT:** This register contains the data to be transmitted or received on the I2C bus. If you are writing to this register and want to perform a read, bits 7:0 (DAT) are ignored by the DW_apb_i2c. However, when you read this register, these bits return the value of data received on the DW_apb_i2c interface.

9.14.1 I2C Control Register (IC_CON)—Offset 0h

I2C Control Register

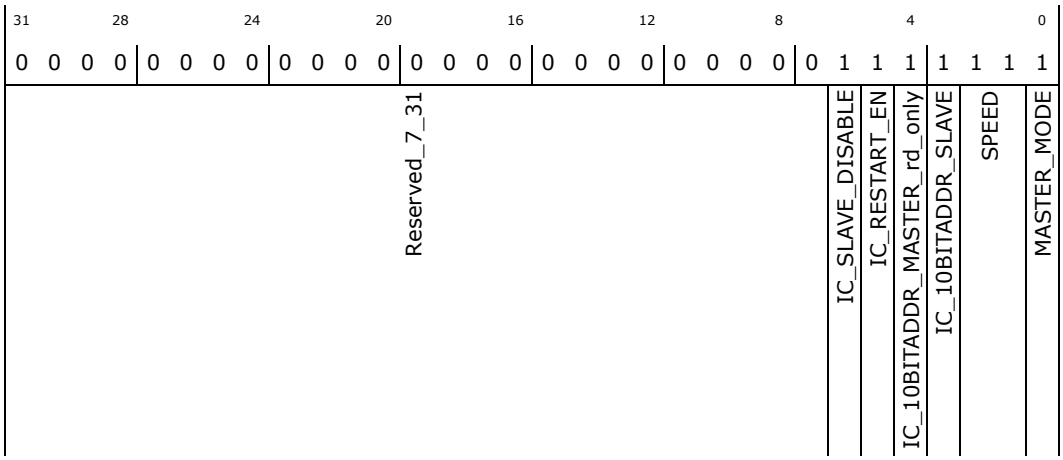
Access Method

Type: Memory Mapped I/O Register (Size: 32 bits)

Offset: [BAR] + 0h

BAR Type: PCI Configuration Register (Size: 32 bits)
BAR Reference: [B:0, D:24, F:2] + 10h

Default: 0000007Fh



Bit Range	Default & Access	Field Name (ID): Description
31:7	0x0 RW	**Reserved_7_31:** Reserved
6	0x1 RW	**IC_SLAVE_DISABLE:** This bit controls whether I2C has its slave disabled. By default, the slave is always enabled (in reset state as well). If you need to disable it after reset, set this bit to 1. If this bit is set (slave is disabled), DW_apb_i2c functions only as a master and does not perform any action that requires a slave.
5	0x1 RW	**IC_RESTART_EN:** Determines whether RESTART conditions may be sent when acting as a master.When the RESTART is disabled, the DW_apb_i2c master is incapable of performing the following functions: Sending a START BYTE. Performing any high-speed mode operation. Performing direction changes in combined format mode. Performing a read operation with a 10-bit address
4	0x1 RO	**IC_10BITADDR_MASTER (IC_10BITADDR_MASTER_rd_only):** controls whether the DW_apb_i2c starts its transfers in 7- or 10-bit addressing mode when acting as a master. If I2C_DYNAMIC_TAR_UPDATE = 1, then this bit is read-only copy of bit 12 of IC_TAR register
3	0x1 RW	**IC_10BITADDR_SLAVE:** When acting as a slave, this bit controls whether the DW_apb_i2c responds to 7- or 10-bit addresses.

Bit Range	Default & Access	Field Name (ID): Description
2:1	0x3 RW	**SPEED:** These bits control at which speed the DW_apb_i2c operates; its setting is relevant only if one is operating the DW_apb_i2c in master mode. Hardware protects against illegal values being programmed by software. This register should be programmed only with a value in the range of 1 to IC_MAX_SPEED_MODE; otherwise, hardware updates this register with the value of IC_MAX_SPEED_MODE.
0	0x1 RW	**MASTER_MODE:** This bit controls whether the DW_apb_i2c master is enabled. Software should ensure that if this bit is set to X, then bit 6 should also be set to X.

9.14.2 I2C Target Address Register (IC_TAR)—Offset 4h

I2C Target Address Register

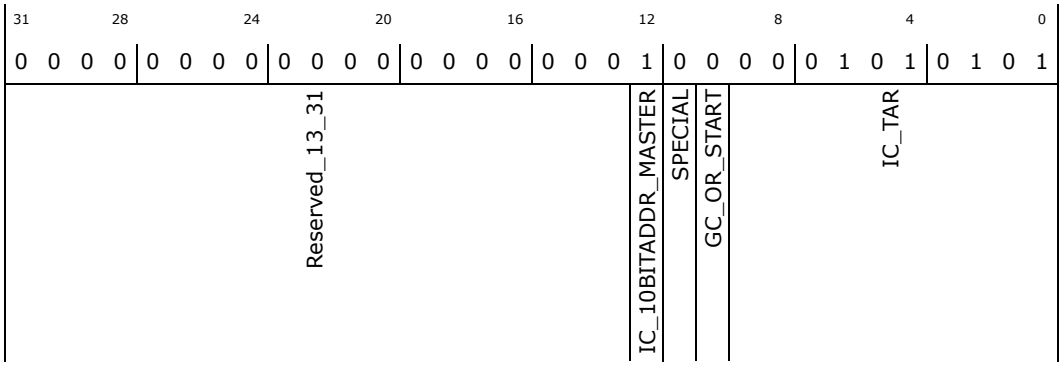
Access Method

Type: Memory Mapped I/O Register (Size: 32 bits)

Offset: [BAR] + 4h

BAR Type: PCI Configuration Register (Size: 32 bits)
BAR Reference: [B:0, D:24, F:2] + 10h

Default: 00001055h



Bit Range	Default & Access	Field Name (ID): Description
31:13	0x0 RW	**Reserved_13_31:** Reserved
12	0x1 RW	**IC_10BITADDR_MASTER:** This bit controls whether the DW_apb_i2c starts its transfers in 7-or 10-bit addressing mode when acting as a master. This bit exists in this register only if the I2C_DYNAMIC_TAR_UPDATE configuration parameter is set to 1
11	0x0 RW	**SPECIAL:** This bit indicates whether software performs a General Call or START BYTE command. 0: ignore bit 10 GC_OR_START and use IC_TAR normally. 1: perform special I2C command as specified in GC_OR_START bit
10	0x0 RW	**GC_OR_START:** If bit 11 (SPECIAL) is set to 1, then this bit indicates whether a General Call(0) or START(1) byte command is to be performed by the DW_apb_i2c.

Bit Range	Default & Access	Field Name (ID): Description
9:0	0x55 RW	**IC_TAR:** This is the target address for any master transaction. When transmitting a General Call, these bits are ignored. To generate a START BYTE, the CPU needs to write only once into these bits.

9.14.3 I2C Slave Address Register (IC_SAR)—Offset 8h

I2C Slave Address Register

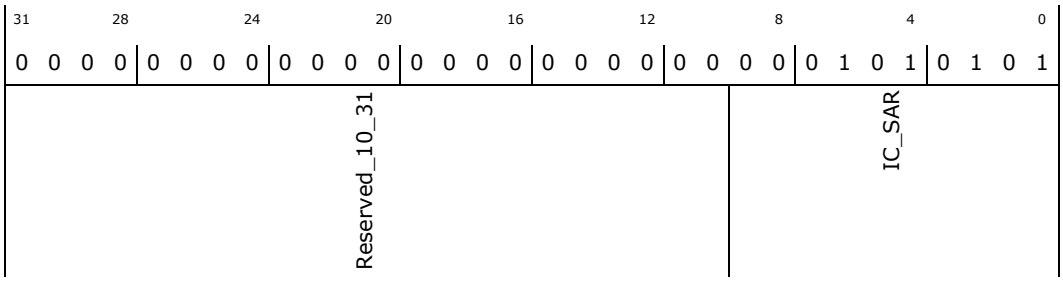
Access Method

Type: Memory Mapped I/O Register (Size: 32 bits)

Offset: [BAR] + 8h

BAR Type: PCI Configuration Register (Size: 32 bits)
BAR Reference: [B:0, D:24, F:2] + 10h

Default: 00000055h



Bit Range	Default & Access	Field Name (ID): Description
31:10	0x0 RW	**Reserved_10_31:** Reserved
9:0	0x55 RW	**IC_SAR:** The IC_SAR holds the slave address when the I2C is operating as a slave. For 7-bit addressing, only IC_SAR[6:0] is used. This register can be written only when the I2C interface is disabled, which corresponds to the IC_ENABLE register being set to 0. Writes at other times have no effect.

9.14.4 I2C High Speed Master Mode Code Address Register (IC_HS_MADDR)—Offset Ch

I2C High Speed Master Mode Code Address Register

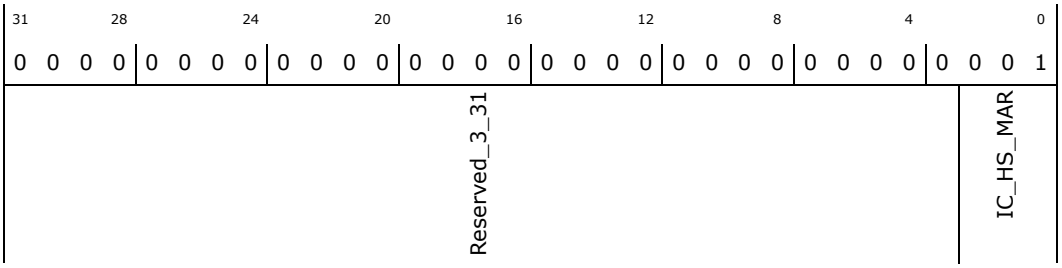
Access Method

Type: Memory Mapped I/O Register (Size: 32 bits)

Offset: [BAR] + Ch

BAR Type: PCI Configuration Register (Size: 32 bits)
BAR Reference: [B:0, D:24, F:2] + 10h

Default: 00000001h



Bit Range	Default & Access	Field Name (ID): Description
31:3	0x0 RW	**Reserved_3_31:** Reserved
2:0	0x1 RW	**IC_HS_MAR:** This bit field holds the value of the I2C HS mode master code. HS-mode master codes are reserved 8-bit codes (00001xxx) that are not used for slave addressing or other purposes. Each master has its unique master code; up to eight highspeed mode masters can be present on the same I2C bus system. Valid values are from 0 to 7. This register goes away and becomes read-only returning 0s if the IC_MAX_SPEED_MODE configuration parameter is set to either Standard (1) or Fast (2). This register can be written only when the I2C interface is disabled, which corresponds to the IC_ENABLE register being set to 0. Writes at other times have no effect.

9.14.5 I2C Rx/Tx Data Buffer and Command Register (IC_DATA_CMD)—Offset 10h

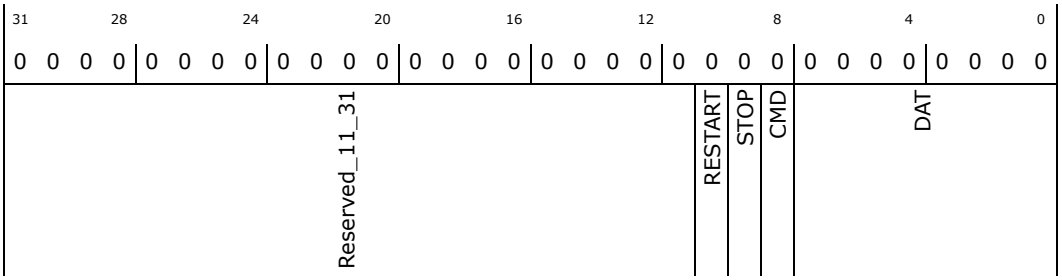
BAR Type: PCI Configuration Register (Size: 32 bits)
BAR Reference: [B:0, D:24, F:2] + 10h

Default: 00000000h



Bit Range	Default & Access	Field Name (ID): Description
31:11	0x0 RW	**Reserved_11_31:** Reserved
10	0x0 RW	**RESTART:** RESTART
9	0x0 RW	**STOP:** STOP
8	0x0 RW	**CMD:** This bit controls whether a read or a write is performed. This bit does not control the direction when the DW_apb_i2c acts as a slave. It controls only the direction when it acts as a master. 1 = Read. 0 = Write
7:0	0x0 RW	**DAT:** This register contains the data to be transmitted or received on the I2C bus. If you are writing to this register and want to perform a read, bits 7:0 (DAT) are ignored by the DW_apb_i2c. However, when you read this register, these bits return the value of data received on the DW_apb_i2c interface.

9.16.1 I2C Control Register (IC_CON)—Offset 0h

I2C Control Register

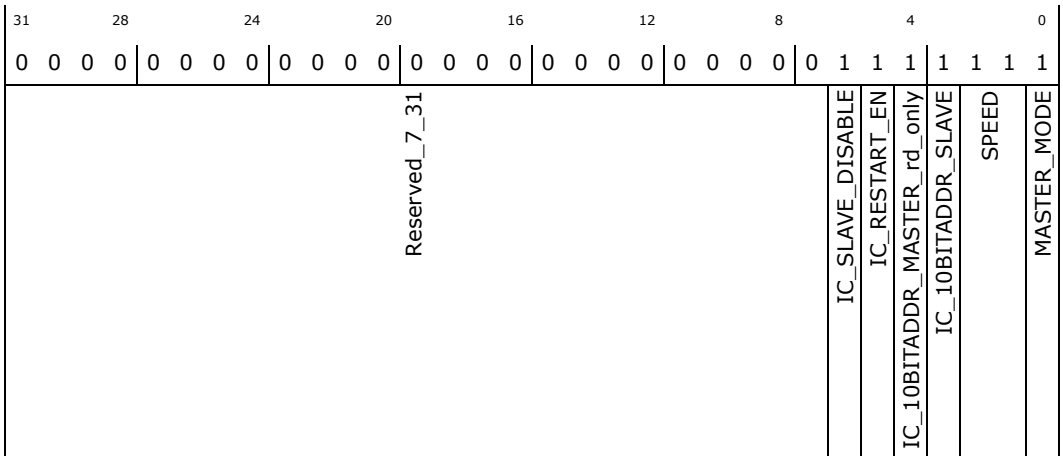
Access Method

Type: Memory Mapped I/O Register (Size: 32 bits)

Offset: [BAR] + 0h

BAR Type: PCI Configuration Register (Size: 32 bits)
BAR Reference: [B:0, D:24, F:3] + 10h

Default: 0000007Fh



Bit Range	Default & Access	Field Name (ID): Description
31:7	0x0 RW	**Reserved_7_31:** Reserved
6	0x1 RW	**IC_SLAVE_DISABLE:** This bit controls whether I2C has its slave disabled. By default, the slave is always enabled (in reset state as well). If you need to disable it after reset, set this bit to 1. If this bit is set (slave is disabled), DW_apb_i2c functions only as a master and does not perform any action that requires a slave.
5	0x1 RW	**IC_RESTART_EN:** Determines whether RESTART conditions may be sent when acting as a master.When the RESTART is disabled, the DW_apb_i2c master is incapable of performing the following functions: Sending a START BYTE. Performing any high-speed mode operation. Performing direction changes in combined format mode. Performing a read operation with a 10-bit address
4	0x1 RO	**IC_10BITADDR_MASTER (IC_10BITADDR_MASTER_rd_only):** controls whether the DW_apb_i2c starts its transfers in 7- or 10-bit addressing mode when acting as a master. If I2C_DYNAMIC_TAR_UPDATE = 1, then this bit is read-only copy of bit 12 of IC_TAR register
3	0x1 RW	**IC_10BITADDR_SLAVE:** When acting as a slave, this bit controls whether the DW_apb_i2c responds to 7- or 10-bit addresses.

Bit Range	Default & Access	Field Name (ID): Description
2:1	0x3 RW	**SPEED:** These bits control at which speed the DW_apb_i2c operates; its setting is relevant only if one is operating the DW_apb_i2c in master mode. Hardware protects against illegal values being programmed by software. This register should be programmed only with a value in the range of 1 to IC_MAX_SPEED_MODE; otherwise, hardware updates this register with the value of IC_MAX_SPEED_MODE.
0	0x1 RW	**MASTER_MODE:** This bit controls whether the DW_apb_i2c master is enabled. Software should ensure that if this bit is set to X, then bit 6 should also be set to X.

9.16.2 I2C Target Address Register (IC_TAR)—Offset 4h

I2C Target Address Register

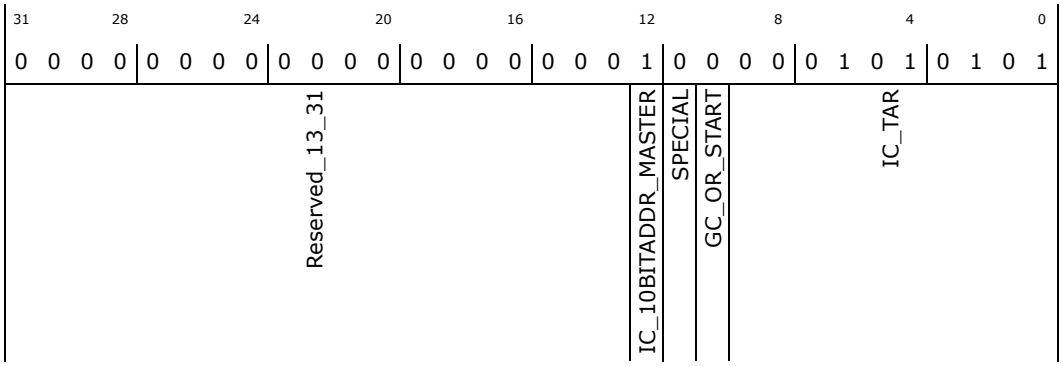
Access Method

Type: Memory Mapped I/O Register (Size: 32 bits)

Offset: [BAR] + 4h

BAR Type: PCI Configuration Register (Size: 32 bits)
BAR Reference: [B:0, D:24, F:3] + 10h

Default: 00001055h



Bit Range	Default & Access	Field Name (ID): Description
31:13	0x0 RW	**Reserved_13_31:** Reserved
12	0x1 RW	**IC_10BITADDR_MASTER:** This bit controls whether the DW_apb_i2c starts its transfers in 7-or 10-bit addressing mode when acting as a master. This bit exists in this register only if the I2C_DYNAMIC_TAR_UPDATE configuration parameter is set to 1
11	0x0 RW	**SPECIAL:** This bit indicates whether software performs a General Call or START BYTE command. 0: ignore bit 10 GC_OR_START and use IC_TAR normally. 1: perform special I2C command as specified in GC_OR_START bit
10	0x0 RW	**GC_OR_START:** If bit 11 (SPECIAL) is set to 1, then this bit indicates whether a General Call(0) or START(1) byte command is to be performed by the DW_apb_i2c.

Bit Range	Default & Access	Field Name (ID): Description
9:0	0x55 RW	**IC_TAR:** This is the target address for any master transaction. When transmitting a General Call, these bits are ignored. To generate a START BYTE, the CPU needs to write only once into these bits.

9.16.3 I2C Slave Address Register (IC_SAR)—Offset 8h

I2C Slave Address Register

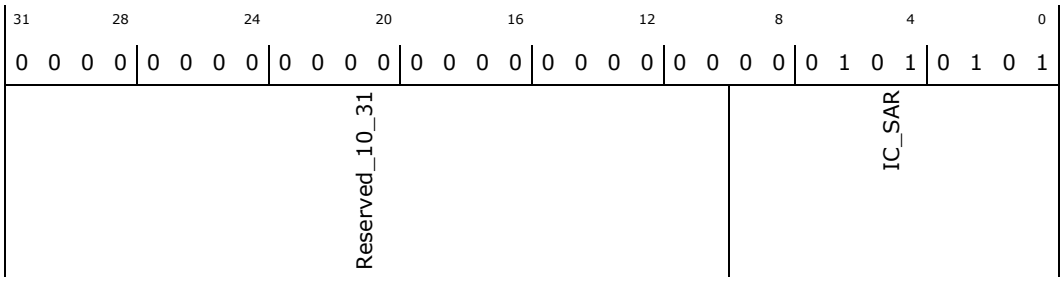
Access Method

Type: Memory Mapped I/O Register (Size: 32 bits)

Offset: [BAR] + 8h

BAR Type: PCI Configuration Register (Size: 32 bits)
BAR Reference: [B:0, D:24, F:3] + 10h

Default: 00000055h



Bit Range	Default & Access	Field Name (ID): Description
31:10	0x0 RW	**Reserved_10_31:** Reserved
9:0	0x55 RW	**IC_SAR:** The IC_SAR holds the slave address when the I2C is operating as a slave. For 7-bit addressing, only IC_SAR[6:0] is used. This register can be written only when the I2C interface is disabled, which corresponds to the IC_ENABLE register being set to 0. Writes at other times have no effect.

9.16.4 I2C High Speed Master Mode Code Address Register (IC_HS_MADDR)—Offset Ch

I2C High Speed Master Mode Code Address Register

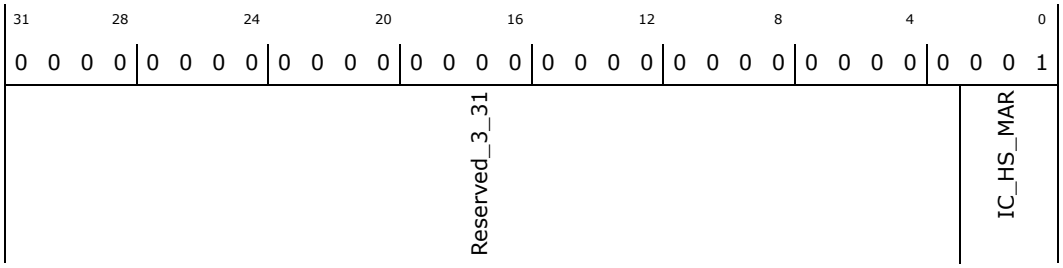
Access Method

Type: Memory Mapped I/O Register (Size: 32 bits)

Offset: [BAR] + Ch

BAR Type: PCI Configuration Register (Size: 32 bits)
BAR Reference: [B:0, D:24, F:3] + 10h

Default: 00000001h



Bit Range	Default & Access	Field Name (ID): Description
31:3	0x0 RW	**Reserved_3_31:** Reserved
2:0	0x1 RW	**IC_HS_MAR:** This bit field holds the value of the I2C HS mode master code. HS-mode master codes are reserved 8-bit codes (00001xxx) that are not used for slave addressing or other purposes. Each master has its unique master code; up to eight highspeed mode masters can be present on the same I2C bus system. Valid values are from 0 to 7. This register goes away and becomes read-only returning 0s if the IC_MAX_SPEED_MODE configuration parameter is set to either Standard (1) or Fast (2). This register can be written only when the I2C interface is disabled, which corresponds to the IC_ENABLE register being set to 0. Writes at other times have no effect.

9.16.5 I2C Rx/Tx Data Buffer and Command Register (IC_DATA_CMD)—Offset 10h

10	0x0 RW	**RESTART:** RESTART
9	0x0 RW	**STOP:** STOP
8	0x0 RW	**CMD:** This bit controls whether a read or a write is performed. This bit does not control the direction when the DW_apb_i2c acts as a slave. It controls only the direction when it acts as a master. 1 = Read. 0 = Write
7:0	0x0 RW	**DAT:** This register contains the data to be transmitted or received on the I2C bus. If you are writing to this register and want to perform a read, bits 7:0 (DAT) are ignored by the DW_apb_i2c. However, when you read this register, these bits return the value of data received on the DW_apb_i2c interface.

9.18.1 I2C Control Register (IC_CON)—Offset 0h

I2C Control Register

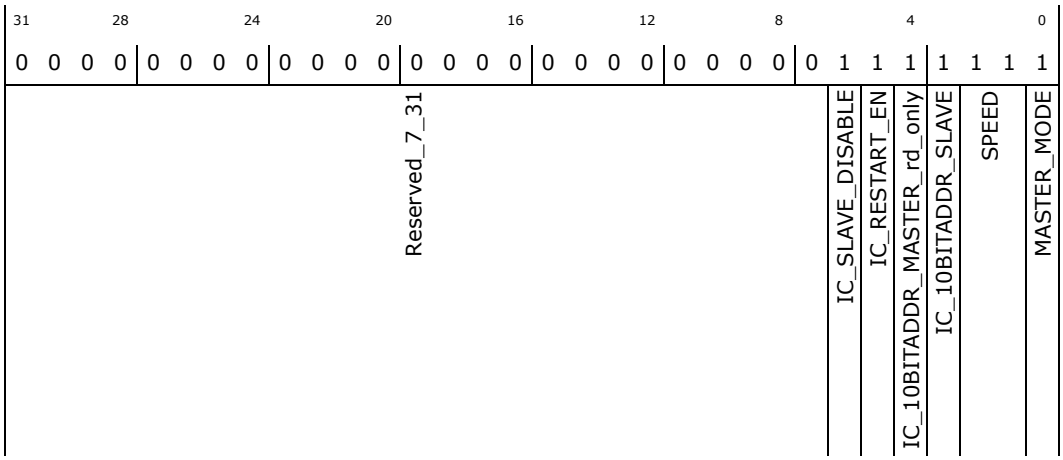
Access Method

Type: Memory Mapped I/O Register (Size: 32 bits)

Offset: [BAR] + 0h

BAR Type: PCI Configuration Register (Size: 32 bits)
BAR Reference: [B:0, D:24, F:4] + 10h

Default: 0000007Fh



Bit Range	Default & Access	Field Name (ID): Description
31:7	0x0 RW	**Reserved_7_31:** Reserved
6	0x1 RW	**IC_SLAVE_DISABLE:** This bit controls whether I2C has its slave disabled. By default, the slave is always enabled (in reset state as well). If you need to disable it after reset, set this bit to 1. If this bit is set (slave is disabled), DW_apb_i2c functions only as a master and does not perform any action that requires a slave.
5	0x1 RW	**IC_RESTART_EN:** Determines whether RESTART conditions may be sent when acting as a master.When the RESTART is disabled, the DW_apb_i2c master is incapable of performing the following functions: Sending a START BYTE. Performing any high-speed mode operation. Performing direction changes in combined format mode. Performing a read operation with a 10-bit address
4	0x1 RO	**IC_10BITADDR_MASTER (IC_10BITADDR_MASTER_rd_only):** controls whether the DW_apb_i2c starts its transfers in 7- or 10-bit addressing mode when acting as a master. If I2C_DYNAMIC_TAR_UPDATE = 1, then this bit is read-only copy of bit 12 of IC_TAR register
3	0x1 RW	**IC_10BITADDR_SLAVE:** When acting as a slave, this bit controls whether the DW_apb_i2c responds to 7- or 10-bit addresses.

Bit Range	Default & Access	Field Name (ID): Description
2:1	0x3 RW	**SPEED:** These bits control at which speed the DW_apb_i2c operates; its setting is relevant only if one is operating the DW_apb_i2c in master mode. Hardware protects against illegal values being programmed by software. This register should be programmed only with a value in the range of 1 to IC_MAX_SPEED_MODE; otherwise, hardware updates this register with the value of IC_MAX_SPEED_MODE.
0	0x1 RW	**MASTER_MODE:** This bit controls whether the DW_apb_i2c master is enabled. Software should ensure that if this bit is set to X, then bit 6 should also be set to X.

9.18.2 I2C Target Address Register (IC_TAR)—Offset 4h

I2C Target Address Register

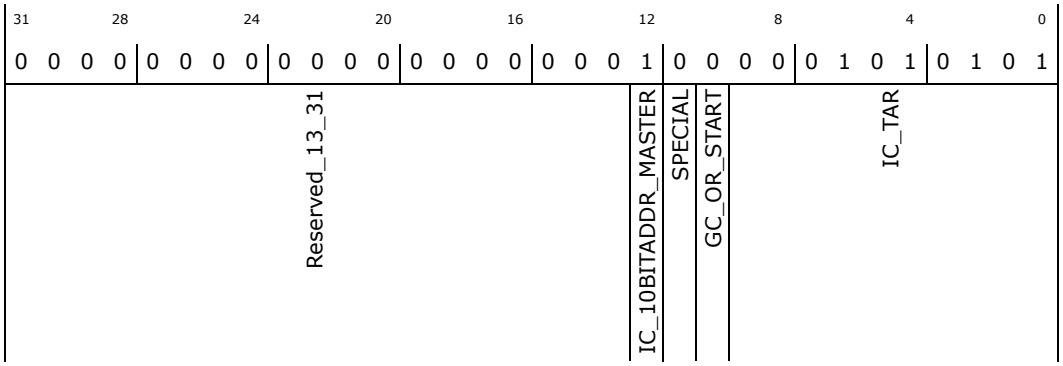
Access Method

Type: Memory Mapped I/O Register (Size: 32 bits)

Offset: [BAR] + 4h

BAR Type: PCI Configuration Register (Size: 32 bits)
BAR Reference: [B:0, D:24, F:4] + 10h

Default: 00001055h



Bit Range	Default & Access	Field Name (ID): Description
31:13	0x0 RW	**Reserved_13_31:** Reserved
12	0x1 RW	**IC_10BITADDR_MASTER:** This bit controls whether the DW_apb_i2c starts its transfers in 7-or 10-bit addressing mode when acting as a master. This bit exists in this register only if the I2C_DYNAMIC_TAR_UPDATE configuration parameter is set to 1
11	0x0 RW	**SPECIAL:** This bit indicates whether software performs a General Call or START BYTE command. 0: ignore bit 10 GC_OR_START and use IC_TAR normally. 1: perform special I2C command as specified in GC_OR_START bit
10	0x0 RW	**GC_OR_START:** If bit 11 (SPECIAL) is set to 1, then this bit indicates whether a General Call(0) or START(1) byte command is to be performed by the DW_apb_i2c.

Bit Range	Default & Access	Field Name (ID): Description
9:0	0x55 RW	**IC_TAR:** This is the target address for any master transaction. When transmitting a General Call, these bits are ignored. To generate a START BYTE, the CPU needs to write only once into these bits.

9.18.3 I2C Slave Address Register (IC_SAR)—Offset 8h

I2C Slave Address Register

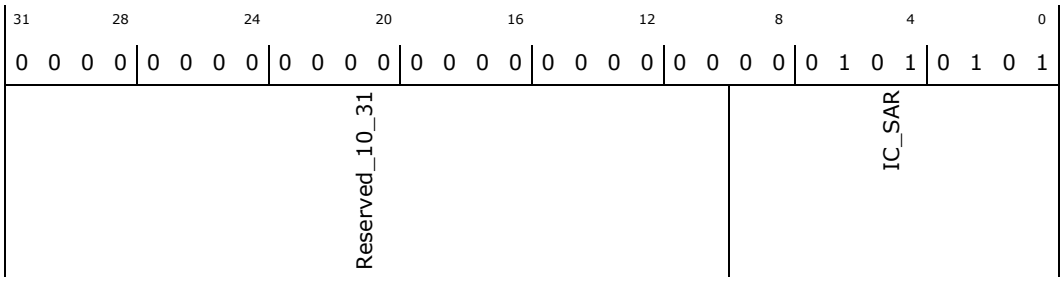
Access Method

Type: Memory Mapped I/O Register (Size: 32 bits)

Offset: [BAR] + 8h

BAR Type: PCI Configuration Register (Size: 32 bits)
BAR Reference: [B:0, D:24, F:4] + 10h

Default: 00000055h



Bit Range	Default & Access	Field Name (ID): Description
31:10	0x0 RW	**Reserved_10_31:** Reserved
9:0	0x55 RW	**IC_SAR:** The IC_SAR holds the slave address when the I2C is operating as a slave. For 7-bit addressing, only IC_SAR[6:0] is used. This register can be written only when the I2C interface is disabled, which corresponds to the IC_ENABLE register being set to 0. Writes at other times have no effect.

9.18.4 I2C High Speed Master Mode Code Address Register (IC_HS_MADDR)—Offset Ch

I2C High Speed Master Mode Code Address Register

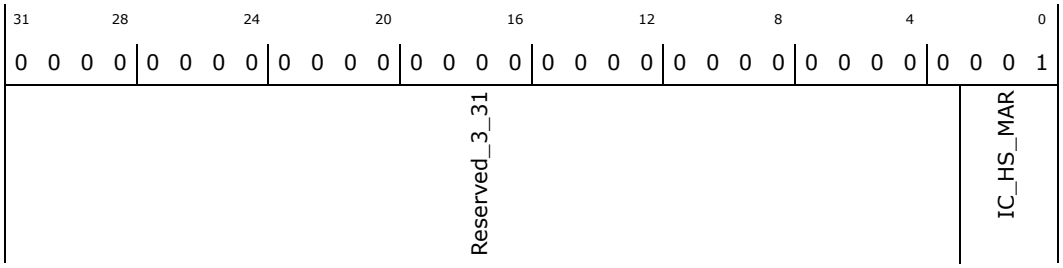
Access Method

Type: Memory Mapped I/O Register (Size: 32 bits)

Offset: [BAR] + Ch

BAR Type: PCI Configuration Register (Size: 32 bits)
BAR Reference: [B:0, D:24, F:4] + 10h

Default: 00000001h



Bit Range	Default & Access	Field Name (ID): Description
31:3	0x0 RW	**Reserved_3_31:** Reserved
2:0	0x1 RW	**IC_HS_MAR:** This bit field holds the value of the I2C HS mode master code. HS-mode master codes are reserved 8-bit codes (00001xxx) that are not used for slave addressing or other purposes. Each master has its unique master code; up to eight highspeed mode masters can be present on the same I2C bus system. Valid values are from 0 to 7. This register goes away and becomes read-only returning 0s if the IC_MAX_SPEED_MODE configuration parameter is set to either Standard (1) or Fast (2). This register can be written only when the I2C interface is disabled, which corresponds to the IC_ENABLE register being set to 0. Writes at other times have no effect.

9.18.5 I2C Rx/Tx Data Buffer and Command Register (IC_DATA_CMD)—Offset 10h

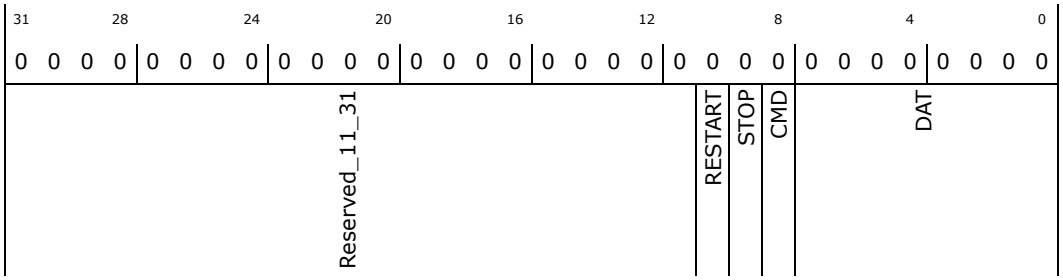
BAR Type: PCI Configuration Register (Size: 32 bits)
BAR Reference: [B:0, D:24, F:4] + 10h

Default: 00000000h



Bit Range	Default & Access	Field Name (ID): Description
31:11	0x0 RW	**Reserved_11_31:** Reserved
10	0x0 RW	**RESTART:** RESTART
9	0x0 RW	**STOP:** STOP
8	0x0 RW	**CMD:** This bit controls whether a read or a write is performed. This bit does not control the direction when the DW_apb_i2c acts as a slave. It controls only the direction when it acts as a master. 1 = Read. 0 = Write
7:0	0x0 RW	**DAT:** This register contains the data to be transmitted or received on the I2C bus. If you are writing to this register and want to perform a read, bits 7:0 (DAT) are ignored by the DW_apb_i2c. However, when you read this register, these bits return the value of data received on the DW_apb_i2c interface.

Bit Range	Default & Access	Field Name (ID): Description
31:16	0x0 RO	**Reserved0:** Reserved
15	0x0 RW/1C	**PMESTATUS:** PME Status: 0 = Software clears the bit by writing a 1 to it. 1 = This bit is set when the AHB Device would normally assert the PME# signal independent of the state of the PME Enable bit (bit 8 in this register)
14:9	0x0 RO	**Reserved1:** Reserved
8	0x0 RW	**PMEENABLE:** PME Enable: A 1 enables the function to assert PME#. When 0, PME# message on SB is disabled.
7:4	0x0 RO	**Reserved2:** Reserved
3	0x1 RO	**NO_SOFT_RESET:** No_Soft_Reset: This bit indicates that devices transitioning from D3hot to D0 because of PowerState commands do not perform an internal reset. Configuration Context is preserved.
2	0x0 RO	**Reserved3:** Reserved
1:0	0x0 RW	**POWERSTATE:** Power State : This field is used both to determine the current power state of the AHB IP and to set a new power state. The values are: 00 = D0 state 11 = D3HOT state Others = Reserved Notes: If software attempts to write a value of 01b or 10b in to this field, the write operation must complete normally; however, the data is discarded and no state change occurs. When in the D3HOT states, interrupts are blocked. D3Hot will not be used for Downstream decode on fabric ports.

9.20.1 I2C Control Register (IC_CON)—Offset 0h

I2C Control Register

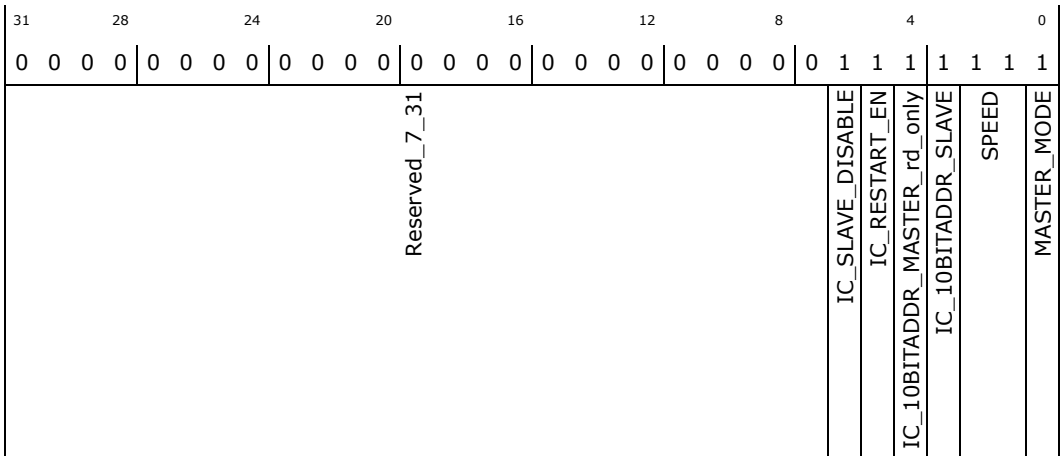
Access Method

Type: Memory Mapped I/O Register (Size: 32 bits)

Offset: [BAR] + 0h

BAR Type: PCI Configuration Register (Size: 32 bits)
BAR Reference: [B:0, D:24, F:5] + 10h

Default: 0000007Fh



Bit Range	Default & Access	Field Name (ID): Description
31:7	0x0 RW	**Reserved_7_31:** Reserved
6	0x1 RW	**IC_SLAVE_DISABLE:** This bit controls whether I2C has its slave disabled. By default, the slave is always enabled (in reset state as well). If you need to disable it after reset, set this bit to 1. If this bit is set (slave is disabled), DW_apb_i2c functions only as a master and does not perform any action that requires a slave.
5	0x1 RW	**IC_RESTART_EN:** Determines whether RESTART conditions may be sent when acting as a master.When the RESTART is disabled, the DW_apb_i2c master is incapable of performing the following functions: Sending a START BYTE. Performing any high-speed mode operation. Performing direction changes in combined format mode. Performing a read operation with a 10-bit address
4	0x1 RO	**IC_10BITADDR_MASTER (IC_10BITADDR_MASTER_rd_only):** controls whether the DW_apb_i2c starts its transfers in 7- or 10-bit addressing mode when acting as a master. If I2C_DYNAMIC_TAR_UPDATE = 1, then this bit is read-only copy of bit 12 of IC_TAR register
3	0x1 RW	**IC_10BITADDR_SLAVE:** When acting as a slave, this bit controls whether the DW_apb_i2c responds to 7- or 10-bit addresses.

Bit Range	Default & Access	Field Name (ID): Description
2:1	0x3 RW	**SPEED:** These bits control at which speed the DW_apb_i2c operates; its setting is relevant only if one is operating the DW_apb_i2c in master mode. Hardware protects against illegal values being programmed by software. This register should be programmed only with a value in the range of 1 to IC_MAX_SPEED_MODE; otherwise, hardware updates this register with the value of IC_MAX_SPEED_MODE.
0	0x1 RW	**MASTER_MODE:** This bit controls whether the DW_apb_i2c master is enabled. Software should ensure that if this bit is set to X, then bit 6 should also be set to X.

9.20.2 I2C Target Address Register (IC_TAR)—Offset 4h

I2C Target Address Register

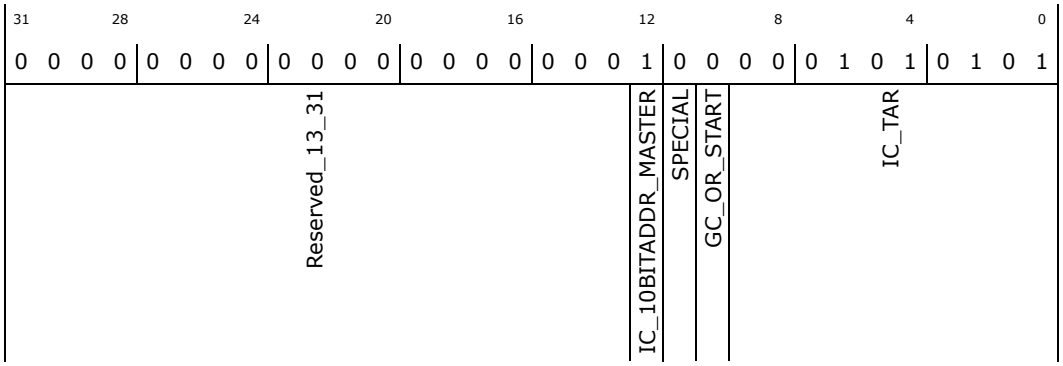
Access Method

Type: Memory Mapped I/O Register (Size: 32 bits)

Offset: [BAR] + 4h

BAR Type: PCI Configuration Register (Size: 32 bits)
BAR Reference: [B:0, D:24, F:5] + 10h

Default: 00001055h



Bit Range	Default & Access	Field Name (ID): Description
31:13	0x0 RW	**Reserved_13_31:** Reserved
12	0x1 RW	**IC_10BITADDR_MASTER:** This bit controls whether the DW_apb_i2c starts its transfers in 7-or 10-bit addressing mode when acting as a master. This bit exists in this register only if the I2C_DYNAMIC_TAR_UPDATE configuration parameter is set to 1
11	0x0 RW	**SPECIAL:** This bit indicates whether software performs a General Call or START BYTE command. 0: ignore bit 10 GC_OR_START and use IC_TAR normally. 1: perform special I2C command as specified in GC_OR_START bit
10	0x0 RW	**GC_OR_START:** If bit 11 (SPECIAL) is set to 1, then this bit indicates whether a General Call(0) or START(1) byte command is to be performed by the DW_apb_i2c.

Bit Range	Default & Access	Field Name (ID): Description
9:0	0x55 RW	**IC_TAR:** This is the target address for any master transaction. When transmitting a General Call, these bits are ignored. To generate a START BYTE, the CPU needs to write only once into these bits.

9.20.3 I2C Slave Address Register (IC_SAR)—Offset 8h

I2C Slave Address Register

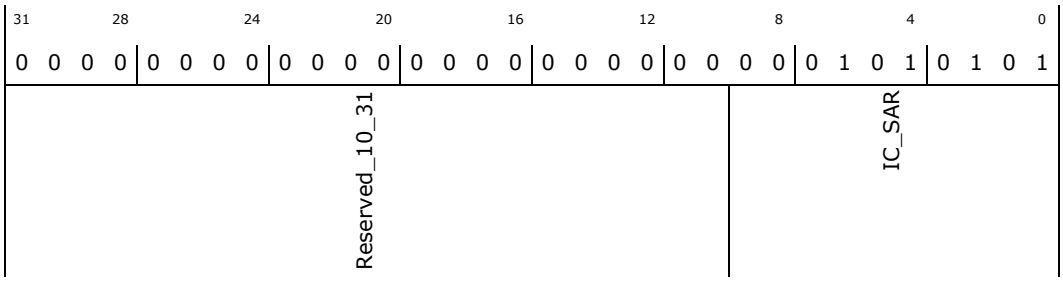
Access Method

Type: Memory Mapped I/O Register (Size: 32 bits)

Offset: [BAR] + 8h

BAR Type: PCI Configuration Register (Size: 32 bits)
BAR Reference: [B:0, D:24, F:5] + 10h

Default: 00000055h



Bit Range	Default & Access	Field Name (ID): Description
31:10	0x0 RW	**Reserved_10_31:** Reserved
9:0	0x55 RW	**IC_SAR:** The IC_SAR holds the slave address when the I2C is operating as a slave. For 7-bit addressing, only IC_SAR[6:0] is used. This register can be written only when the I2C interface is disabled, which corresponds to the IC_ENABLE register being set to 0. Writes at other times have no effect.

9.20.4 I2C High Speed Master Mode Code Address Register (IC_HS_MADDR)—Offset Ch

I2C High Speed Master Mode Code Address Register

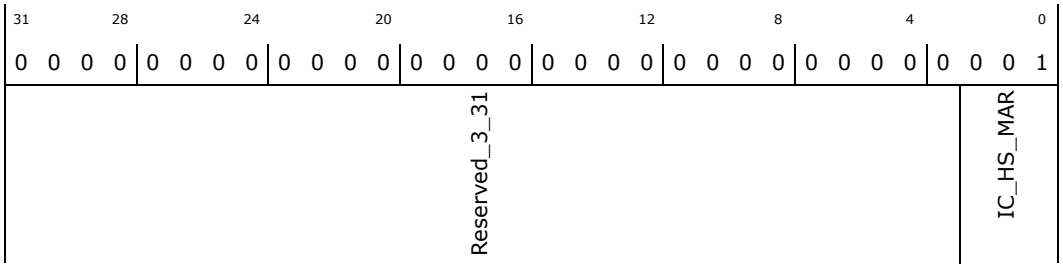
Access Method

Type: Memory Mapped I/O Register (Size: 32 bits)

Offset: [BAR] + Ch

BAR Type: PCI Configuration Register (Size: 32 bits)
BAR Reference: [B:0, D:24, F:5] + 10h

Default: 00000001h



Bit Range	Default & Access	Field Name (ID): Description
31:3	0x0 RW	**Reserved_3_31:** Reserved
2:0	0x1 RW	**IC_HS_MAR:** This bit field holds the value of the I2C HS mode master code. HS-mode master codes are reserved 8-bit codes (00001xxx) that are not used for slave addressing or other purposes. Each master has its unique master code; up to eight highspeed mode masters can be present on the same I2C bus system. Valid values are from 0 to 7. This register goes away and becomes read-only returning 0s if the IC_MAX_SPEED_MODE configuration parameter is set to either Standard (1) or Fast (2). This register can be written only when the I2C interface is disabled, which corresponds to the IC_ENABLE register being set to 0. Writes at other times have no effect.

9.20.5 I2C Rx/Tx Data Buffer and Command Register (IC_DATA_CMD)—Offset 10h

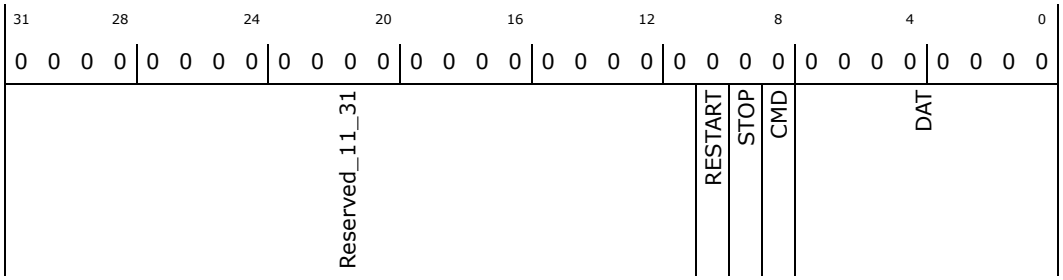
Offset: [BAR] + 10h

BAR Type: PCI Configuration Register (Size: 32 bits)
BAR Reference: [B:0, D:24, F:5] + 10h

Default: 00000000h



Bit Range	Default & Access	Field Name (ID): Description
31:11	0x0 RW	**Reserved_11_31:** Reserved
10	0x0 RW	**RESTART:** RESTART
9	0x0 RW	**STOP:** STOP
8	0x0 RW	**CMD:** This bit controls whether a read or a write is performed. This bit does not control the direction when the DW_apb_i2c acts as a slave. It controls only the direction when it acts as a master. 1 = Read. 0 = Write
7:0	0x0 RW	**DAT:** This register contains the data to be transmitted or received on the I2C bus. If you are writing to this register and want to perform a read, bits 7:0 (DAT) are ignored by the DW_apb_i2c. However, when you read this register, these bits return the value of data received on the DW_apb_i2c interface.

9.22.1 I2C Control Register (IC_CON)—Offset 0h

I2C Control Register

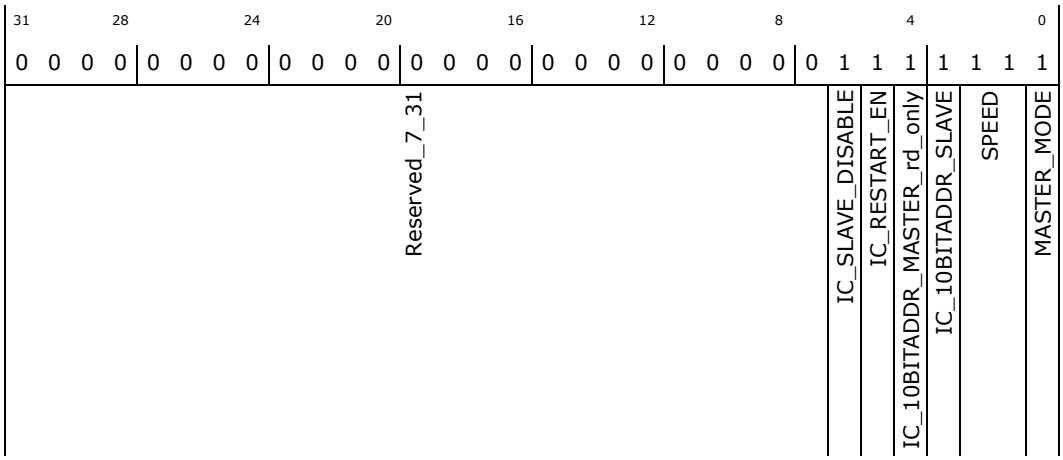
Access Method

Type: Memory Mapped I/O Register (Size: 32 bits)

Offset: [BAR] + 0h

BAR Type: PCI Configuration Register (Size: 32 bits)
BAR Reference: [B:0, D:24, F:6] + 10h

Default: 0000007Fh



Bit Range	Default & Access	Field Name (ID): Description
31:7	0x0 RW	**Reserved_7_31:** Reserved
6	0x1 RW	**IC_SLAVE_DISABLE:** This bit controls whether I2C has its slave disabled. By default, the slave is always enabled (in reset state as well). If you need to disable it after reset, set this bit to 1. If this bit is set (slave is disabled), DW_apb_i2c functions only as a master and does not perform any action that requires a slave.
5	0x1 RW	**IC_RESTART_EN:** Determines whether RESTART conditions may be sent when acting as a master.When the RESTART is disabled, the DW_apb_i2c master is incapable of performing the following functions: Sending a START BYTE. Performing any high-speed mode operation. Performing direction changes in combined format mode. Performing a read operation with a 10-bit address
4	0x1 RO	**IC_10BITADDR_MASTER (IC_10BITADDR_MASTER_rd_only):** controls whether the DW_apb_i2c starts its transfers in 7- or 10-bit addressing mode when acting as a master. If I2C_DYNAMIC_TAR_UPDATE = 1, then this bit is read-only copy of bit 12 of IC_TAR register
3	0x1 RW	**IC_10BITADDR_SLAVE:** When acting as a slave, this bit controls whether the DW_apb_i2c responds to 7- or 10-bit addresses.

Bit Range	Default & Access	Field Name (ID): Description
2:1	0x3 RW	**SPEED:** These bits control at which speed the DW_apb_i2c operates; its setting is relevant only if one is operating the DW_apb_i2c in master mode. Hardware protects against illegal values being programmed by software. This register should be programmed only with a value in the range of 1 to IC_MAX_SPEED_MODE; otherwise, hardware updates this register with the value of IC_MAX_SPEED_MODE.
0	0x1 RW	**MASTER_MODE:** This bit controls whether the DW_apb_i2c master is enabled. Software should ensure that if this bit is set to X, then bit 6 should also be set to X.

9.22.2 I2C Target Address Register (IC_TAR)—Offset 4h

I2C Target Address Register

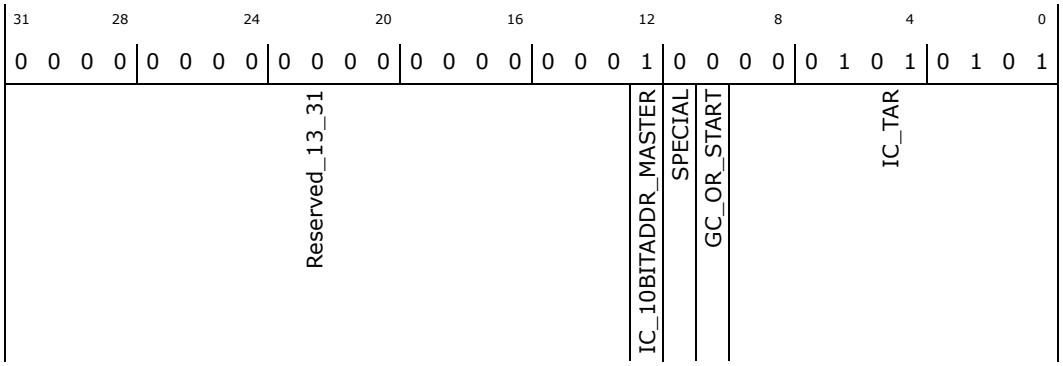
Access Method

Type: Memory Mapped I/O Register (Size: 32 bits)

Offset: [BAR] + 4h

BAR Type: PCI Configuration Register (Size: 32 bits)
BAR Reference: [B:0, D:24, F:6] + 10h

Default: 00001055h



Bit Range	Default & Access	Field Name (ID): Description
31:13	0x0 RW	**Reserved_13_31:** Reserved
12	0x1 RW	**IC_10BITADDR_MASTER:** This bit controls whether the DW_apb_i2c starts its transfers in 7-or 10-bit addressing mode when acting as a master. This bit exists in this register only if the I2C_DYNAMIC_TAR_UPDATE configuration parameter is set to 1
11	0x0 RW	**SPECIAL:** This bit indicates whether software performs a General Call or START BYTE command. 0: ignore bit 10 GC_OR_START and use IC_TAR normally. 1: perform special I2C command as specified in GC_OR_START bit
10	0x0 RW	**GC_OR_START:** If bit 11 (SPECIAL) is set to 1, then this bit indicates whether a General Call(0) or START(1) byte command is to be performed by the DW_apb_i2c.

Bit Range	Default & Access	Field Name (ID): Description
9:0	0x55 RW	**IC_TAR:** This is the target address for any master transaction. When transmitting a General Call, these bits are ignored. To generate a START BYTE, the CPU needs to write only once into these bits.

9.22.3 I2C Slave Address Register (IC_SAR)—Offset 8h

I2C Slave Address Register

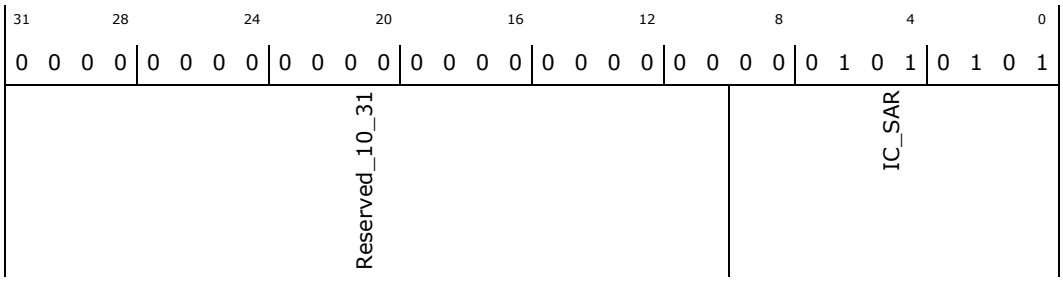
Access Method

Type: Memory Mapped I/O Register (Size: 32 bits)

Offset: [BAR] + 8h

BAR Type: PCI Configuration Register (Size: 32 bits)
BAR Reference: [B:0, D:24, F:6] + 10h

Default: 00000055h



Bit Range	Default & Access	Field Name (ID): Description
31:10	0x0 RW	**Reserved_10_31:** Reserved
9:0	0x55 RW	**IC_SAR:** The IC_SAR holds the slave address when the I2C is operating as a slave. For 7-bit addressing, only IC_SAR[6:0] is used. This register can be written only when the I2C interface is disabled, which corresponds to the IC_ENABLE register being set to 0. Writes at other times have no effect.

9.22.4 I2C High Speed Master Mode Code Address Register (IC_HS_MADDR)—Offset Ch

I2C High Speed Master Mode Code Address Register

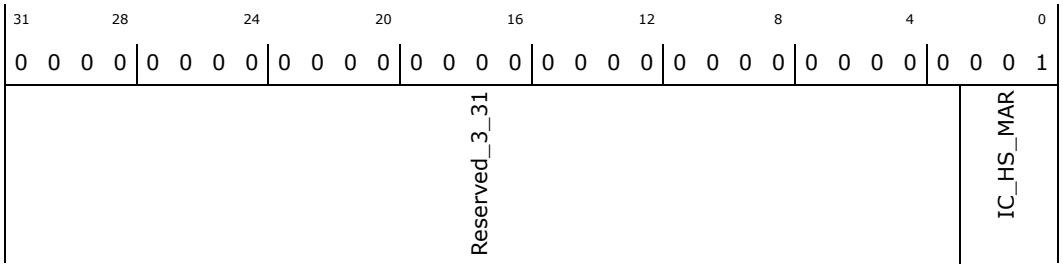
Access Method

Type: Memory Mapped I/O Register (Size: 32 bits)

Offset: [BAR] + Ch

BAR Type: PCI Configuration Register (Size: 32 bits)
BAR Reference: [B:0, D:24, F:6] + 10h

Default: 00000001h



Bit Range	Default & Access	Field Name (ID): Description
31:3	0x0 RW	**Reserved_3_31:** Reserved
2:0	0x1 RW	**IC_HS_MAR:** This bit field holds the value of the I2C HS mode master code. HS-mode master codes are reserved 8-bit codes (00001xxx) that are not used for slave addressing or other purposes. Each master has its unique master code; up to eight highspeed mode masters can be present on the same I2C bus system. Valid values are from 0 to 7. This register goes away and becomes read-only returning 0s if the IC_MAX_SPEED_MODE configuration parameter is set to either Standard (1) or Fast (2). This register can be written only when the I2C interface is disabled, which corresponds to the IC_ENABLE register being set to 0. Writes at other times have no effect.

9.22.5 I2C Rx/Tx Data Buffer and Command Register (IC_DATA_CMD)—Offset 10h

I2C Rx/Tx Data Buffer and Command Register; this is the register the CPU writes to when filling the TX FIFO and the CPU reads from when retrieving bytes from RX FIFO

Access Method

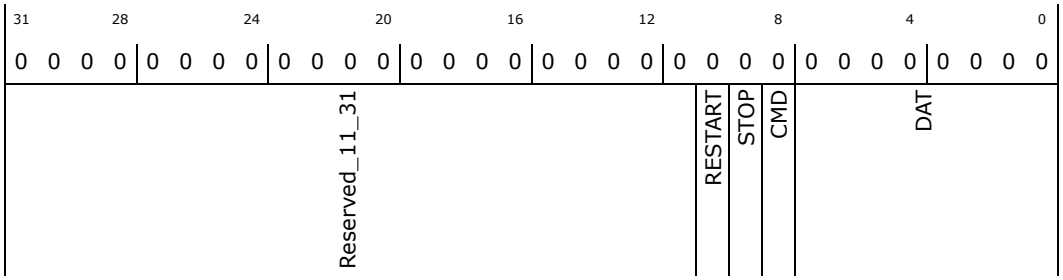
Offset: [BAR] + 10h

BAR Type: PCI Configuration Register (Size: 32 bits)
BAR Reference: [B:0, D:24, F:6] + 10h

Default: 00000000h



Bit Range	Default & Access	Field Name (ID): Description
31:11	0x0 RW	**Reserved_11_31:** Reserved
10	0x0 RW	**RESTART:** RESTART
9	0x0 RW	**STOP:** STOP
8	0x0 RW	**CMD:** This bit controls whether a read or a write is performed. This bit does not control the direction when the DW_apb_i2c acts as a slave. It controls only the direction when it acts as a master. 1 = Read. 0 = Write
7:0	0x0 RW	**DAT:** This register contains the data to be transmitted or received on the I2C bus. If you are writing to this register and want to perform a read, bits 7:0 (DAT) are ignored by the DW_apb_i2c. However, when you read this register, these bits return the value of data received on the DW_apb_i2c interface.

9.24.1 I2C Control Register (IC_CON)—Offset 0h

I2C Control Register

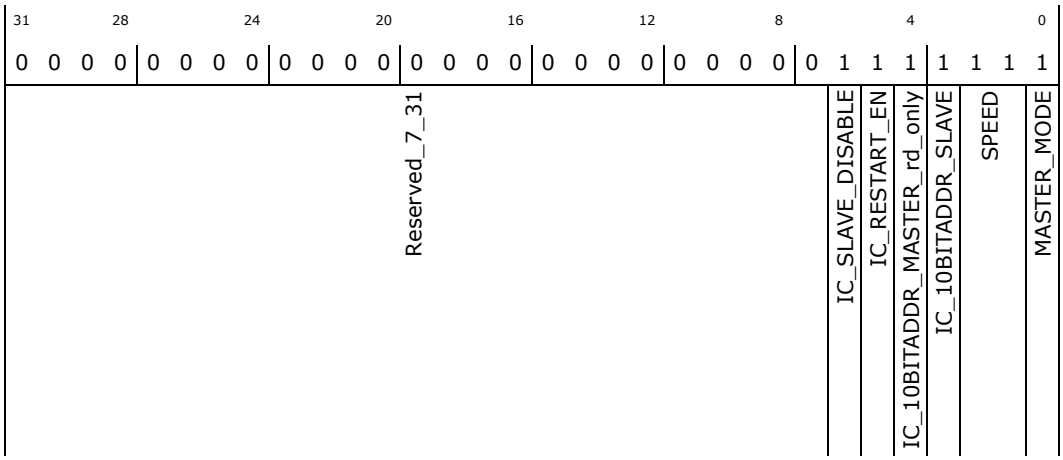
Access Method

Type: Memory Mapped I/O Register (Size: 32 bits)

Offset: [BAR] + 0h

BAR Type: PCI Configuration Register (Size: 32 bits)
BAR Reference: [B:0, D:24, F:7] + 10h

Default: 0000007Fh



Bit Range	Default & Access	Field Name (ID): Description
31:7	0x0 RW	**Reserved_7_31:** Reserved
6	0x1 RW	**IC_SLAVE_DISABLE:** This bit controls whether I2C has its slave disabled. By default, the slave is always enabled (in reset state as well). If you need to disable it after reset, set this bit to 1. If this bit is set (slave is disabled), DW_apb_i2c functions only as a master and does not perform any action that requires a slave.
5	0x1 RW	**IC_RESTART_EN:** Determines whether RESTART conditions may be sent when acting as a master.When the RESTART is disabled, the DW_apb_i2c master is incapable of performing the following functions: Sending a START BYTE. Performing any high-speed mode operation. Performing direction changes in combined format mode. Performing a read operation with a 10-bit address
4	0x1 RO	**IC_10BITADDR_MASTER (IC_10BITADDR_MASTER_rd_only):** controls whether the DW_apb_i2c starts its transfers in 7- or 10-bit addressing mode when acting as a master. If I2C_DYNAMIC_TAR_UPDATE = 1, then this bit is read-only copy of bit 12 of IC_TAR register
3	0x1 RW	**IC_10BITADDR_SLAVE:** When acting as a slave, this bit controls whether the DW_apb_i2c responds to 7- or 10-bit addresses.

Bit Range	Default & Access	Field Name (ID): Description
2:1	0x3 RW	**SPEED:** These bits control at which speed the DW_apb_i2c operates; its setting is relevant only if one is operating the DW_apb_i2c in master mode. Hardware protects against illegal values being programmed by software. This register should be programmed only with a value in the range of 1 to IC_MAX_SPEED_MODE; otherwise, hardware updates this register with the value of IC_MAX_SPEED_MODE.
0	0x1 RW	**MASTER_MODE:** This bit controls whether the DW_apb_i2c master is enabled. Software should ensure that if this bit is set to X, then bit 6 should also be set to X.

9.24.2 I2C Target Address Register (IC_TAR)—Offset 4h

I2C Target Address Register

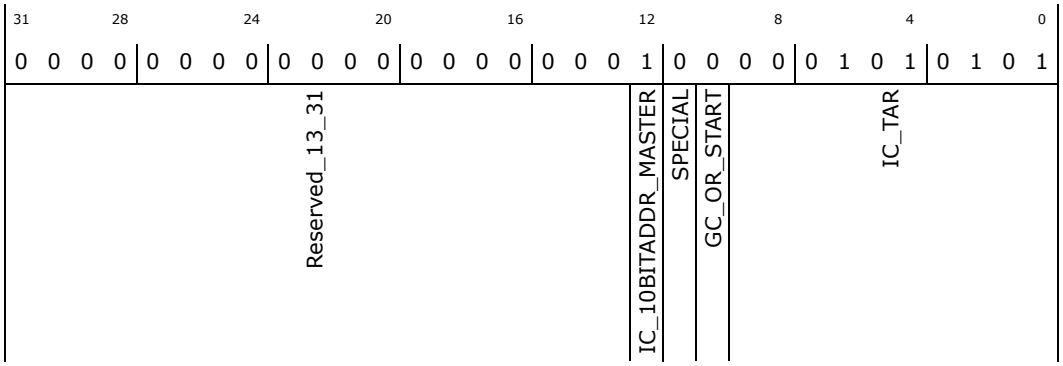
Access Method

Type: Memory Mapped I/O Register (Size: 32 bits)

Offset: [BAR] + 4h

BAR Type: PCI Configuration Register (Size: 32 bits)
BAR Reference: [B:0, D:24, F:7] + 10h

Default: 00001055h



Bit Range	Default & Access	Field Name (ID): Description
31:13	0x0 RW	**Reserved_13_31:** Reserved
12	0x1 RW	**IC_10BITADDR_MASTER:** This bit controls whether the DW_apb_i2c starts its transfers in 7-or 10-bit addressing mode when acting as a master. This bit exists in this register only if the I2C_DYNAMIC_TAR_UPDATE configuration parameter is set to 1
11	0x0 RW	**SPECIAL:** This bit indicates whether software performs a General Call or START BYTE command. 0: ignore bit 10 GC_OR_START and use IC_TAR normally. 1: perform special I2C command as specified in GC_OR_START bit
10	0x0 RW	**GC_OR_START:** If bit 11 (SPECIAL) is set to 1, then this bit indicates whether a General Call(0) or START(1) byte command is to be performed by the DW_apb_i2c.

Bit Range	Default & Access	Field Name (ID): Description
9:0	0x55 RW	**IC_TAR:** This is the target address for any master transaction. When transmitting a General Call, these bits are ignored. To generate a START BYTE, the CPU needs to write only once into these bits.

9.24.3 I2C Slave Address Register (IC_SAR)—Offset 8h

I2C Slave Address Register

Access Method

Type: Memory Mapped I/O Register (Size: 32 bits)

Offset: [BAR] + 8h

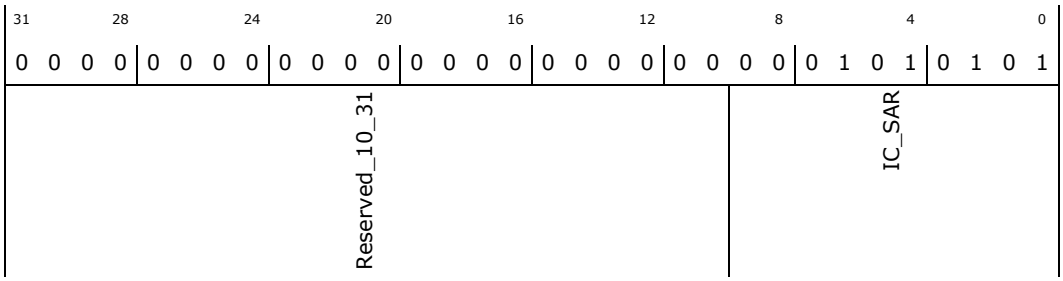
BAR Reference: [B:0, D:24, F:7] + 10h

Default: 00000055h



Bit Range	Default & Access	Field Name (ID): Description
31:10	0x0 RW	**Reserved_10_31:** Reserved
9:0	0x55 RW	**IC_SAR:** The IC_SAR holds the slave address when the I2C is operating as a slave. For 7-bit addressing, only IC_SAR[6:0] is used. This register can be written only when the I2C interface is disabled, which corresponds to the IC_ENABLE register being set to 0. Writes at other times have no effect.

9.24.4 I2C High Speed Master Mode Code Address Register (IC_HS_MADDR)—Offset Ch

I2C High Speed Master Mode Code Address Register

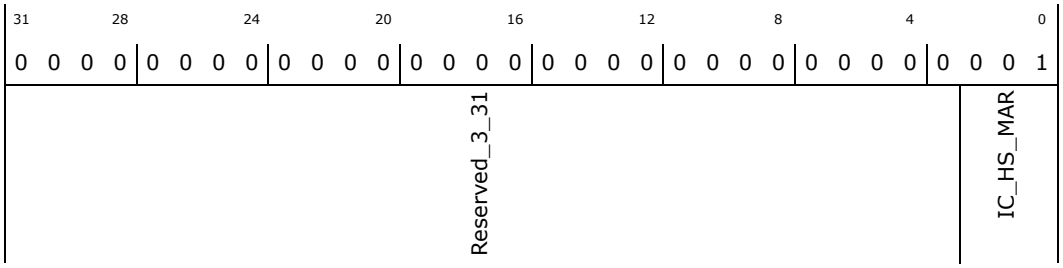
Access Method

Type: Memory Mapped I/O Register (Size: 32 bits)

Offset: [BAR] + Ch

BAR Type: PCI Configuration Register (Size: 32 bits)
BAR Reference: [B:0, D:24, F:7] + 10h

Default: 00000001h



Bit Range	Default & Access	Field Name (ID): Description
31:3	0x0 RW	**Reserved_3_31:** Reserved
2:0	0x1 RW	**IC_HS_MAR:** This bit field holds the value of the I2C HS mode master code. HS-mode master codes are reserved 8-bit codes (00001xxx) that are not used for slave addressing or other purposes. Each master has its unique master code; up to eight highspeed mode masters can be present on the same I2C bus system. Valid values are from 0 to 7. This register goes away and becomes read-only returning 0s if the IC_MAX_SPEED_MODE configuration parameter is set to either Standard (1) or Fast (2). This register can be written only when the I2C interface is disabled, which corresponds to the IC_ENABLE register being set to 0. Writes at other times have no effect.

9.24.5 I2C Rx/Tx Data Buffer and Command Register (IC_DATA_CMD)—Offset 10h

10	0x0 RW	**RESTART:** RESTART
9	0x0 RW	**STOP:** STOP
8	0x0 RW	**CMD:** This bit controls whether a read or a write is performed. This bit does not control the direction when the DW_apb_i2c acts as a slave. It controls only the direction when it acts as a master. 1 = Read. 0 = Write
7:0	0x0 RW	**DAT:** This register contains the data to be transmitted or received on the I2C bus. If you are writing to this register and want to perform a read, bits 7:0 (DAT) are ignored by the DW_apb_i2c. However, when you read this register, these bits return the value of data received on the DW_apb_i2c interface.

Bit Range	Default & Access	Field Name (ID): Description
31:8	0x0 RO	**RSVD0:** Reserved

Bit Range	Default & Access	Field Name (ID): Description
7	0x0 RW	**DLAB:** Divisor Latch Access Bit. If UART_16550_COMPATIBLE == NO, then writeable only when UART is not busy (USR[0] is zero); otherwise always writable, always readable. This bit is used to enable reading and writing of the Divisor Latch register (DLL and DLH) to set the baud rate of the UART. This bit must be cleared after initial baud rate setup in order to access other registers. Reset Value: 0x0
6	0x0 RW	**Break:** Break Control Bit.This is used to cause a break condition to be transmitted to the receiving device. If set to one the serial output is forced to the spacing (logic 0) state. When not in Loopback Mode, as determined by MCR[4], the sout line is forced low until the Break bit is cleared. If SIR_MODE == Enabled and active (MCR[6] set to one) the sir_out_n line is continuously pulsed. When in Loopback Mode, the break condition is internally looped back to the receiver and the sir_out_n line is forced low. Reset Value: 0x0
5	0x0 RO	**RSVD1:** Reserved
4	0x0 RW	**EPS:** Even Parity Select. If UART_16550_COMPATIBLE == NO, then writeable only when UART is not busy (USR[0] is zero); otherwise always writable, always readable. This is used to select between even and odd parity, when parity is enabled (PEN set to one). If set to one, an even number of logic 1s is transmitted or checked. If set to zero, an odd number of logic 1s is transmitted or checked. Reset Value: 0x0
3	0x0 RW	**PEN:** Parity Enable. If UART_16550_COMPATIBLE == NO, then writeable only when UART is not busy (USR[0] is zero); otherwise always writable, always readable. This bit is used to enable and disable parity generation and detection in transmitted and received serial character respectively. 0 = parity disabled 1 = parity enabled Reset Value: 0x0
2	0x0 RW	**STOP:** Number of stop bits. If UART_16550_COMPATIBLE == NO, then writeable only when UART is not busy (USR[0] is zero); otherwise always writable, always readable. This is used to select the number of stop bits per character that the peripheral transmits and receives. If set to zero, one stop bit is transmitted in the serial data. If set to one and the data bits are set to 5 (LCR[1:0] set to zero) one and a half stop bits is transmitted. Otherwise, two stop bits are transmitted. Note that regardless of the number of stop bits selected, the receiver checks only the first stop bit. 0 = 1 stop bit 1 = 1.5 stop bits when DLS (LCR[1:0]) is zero, else 2 stop bit Reset Value: 0x0
1:0	0x0 RW	**DLS:** Data Length Select. If UART_16550_COMPATIBLE == NO, then writeable only when UART is not busy (USR[0] is zero); otherwise always writable, always readable. This is used to select the number of data bits per character that the peripheral transmits and receives. The number of bit that may be selected areas follows: 00 = 5 bits 01 = 6 bits 10 = 7 bits 11 = 8 bits Reset Value: 0x0

9.26.5 Modem Control Register (MCR)—Offset 10h

Modem Control Register

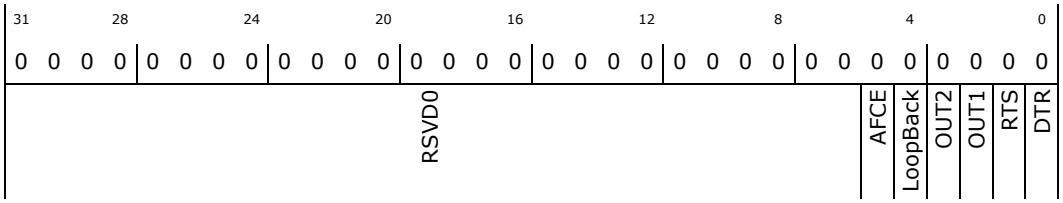
Access Method

Type: Memory Mapped I/O Register (Size: 32 bits)

Offset: [BAR] + 10h

BAR Type: PCI Configuration Register (Size: 32 bits)
BAR Reference: [B:0, D:30, F:3] + 10h

Default: 00000000h



Bit Range	Default & Access	Field Name (ID): Description
31:6	0x0 RO	**RSVD0:** Reserved
5	0x0 RW	**AFCE:** Auto Flow Control Enable. Writeable only when AFCE_MODE == Enabled, always readable. When FIFOs are enabled and the Auto Flow Control Enable (AFCE) bit is set, Auto Flow Control features are enabled as described in Auto Flow Control on page 37. 0 = Auto Flow Control Mode disabled 1 = Auto Flow Control Mode enabled Reset Value: 0x0
4	0x0 RW	**LoopBack:** LoopBack Bit. This is used to put the UART into a diagnostic mode for test purposes. If operating in UART mode (SIR_MODE != Enabled or not active, MCR[6] set to zero), data on the sout line is held high, while serial data output is looped back to the sin line, internally. In this mode all the interrupts are fully functional. Also, in loopback mode, the modem control inputs (dsr_n, cts_n, ri_n, dcd_n) are disconnected and the modem control outputs (dtr_n, rts_n, out1_n, out2_n) are looped back to the inputs, internally. If operating in infrared mode (SIR_MODE == Enabled AND active, MCR[6] set to one), data on the sir_out_n line is held low, while serial data output is inverted and looped back to the sir_in line. Reset Value: 0x0
3	0x0 RW	**OUT2:** OUT2. This is used to directly control the user-designated Output2 (out2_n) output. The value written to this location is inverted and driven out on out2_n, that is: 0 = out2_n de-asserted (logic 1) 1 = out2_n asserted (logic 0) Note that in Loopback mode (MCR[4] set to one), the out2_n output is held inactive high while the value of this location is internally looped back to an input. Reset Value: 0x0
2	0x0 RW	**OUT1:** OUT1. This is used to directly control the user-designated Output1 (out1_n) output. The value written to this location is inverted and driven out on out1_n, that is: 0 = out1_n de-asserted (logic 1) 1 = out1_n asserted (logic 0) Note that in Loopback mode (MCR[4] set to one), the out1_n output is held inactive high while the value of this location is internally looped back to an input. Reset Value: 0x0

Bit Range	Default & Access	Field Name (ID): Description
1	0x0 RW	**RTS:** Request to Send. This is used to directly control the Request to Send (rts_n) output. The Request To Send (rts_n) output is used to inform the modem or data set that the UART is ready to exchange data. When Auto RTS Flow Control is not enabled (MCR[5] set to zero), the rts_n signal is set low by programming MCR[1] (RTS) to a high.In Auto Flow Control, AFCE_MODE == Enabled and active (MCR[5] set to one) and FIFOs enable (FCR[0] set to one), the rts_n output is controlled in the same way, but is also gated with the receiver FIFO threshold trigger (rts_n is inactive high when above the threshold). The rts_n signal is de-asserted when MCR[1] is set low. Note that in Loopback mode (MCR[4] set to one), the rts_n output is held inactive high while the value of this location is internally looped back to an input. Reset Value: 0x0
0	0x0 RW	**DTR:** Data Terminal Ready. This is used to directly control the Data Terminal Ready (dtr_n) output. The value written to this location is inverted and driven out on dtr_n, that is: 0 = dtr_n de-asserted (logic 1) 1 = dtr_n asserted (logic 0) The Data Terminal Ready output is used to inform the modem or data set that the UART is ready to establish communications. Note that in Loopback mode (MCR[4] set to one), the dtr_n output is held inactive high while the value of this location is internally looped back to an input. Reset Value: 0x0

9.26.6 Line Status Register (LSR)—Offset 14h

Line Status Register

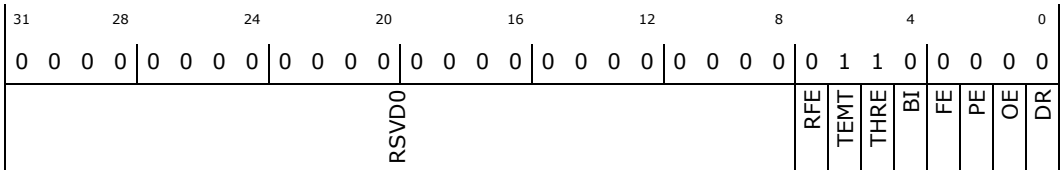
Access Method

Type: Memory Mapped I/O Register (Size: 32 bits)

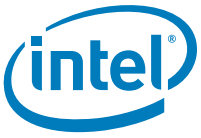
Offset: [BAR] + 14h

BAR Type: PCI Configuration Register (Size: 32 bits)
BAR Reference: [B:0, D:30, F:3] + 10h

Default: 00000060h



Bit Range	Default & Access	Field Name (ID): Description
31:8	0x0 RO	**RSVD0:** Reserved
7	0x0 RO	**RFE:** Receiver FIFO Error bit. This bit is only relevant when FIFO_MODE != NONE AND FIFOs are enabled (FCR[0] set to one). This is used to indicate if there is at least one parity error, framing error, or break indication in the FIFO. 0 = no error in RX FIFO 1 = error in RX FIFO This bit is cleared when the LSR is read and the character with the error is at the top of the receiver FIFO and there are no subsequent errors in the FIFO. Reset Value: 0x0



Bit Range	Default & Access	Field Name (ID): Description
6	0x1 RO	**TEMT:** Transmitter Empty bit. If in FIFO mode (FIFO_MODE != NONE) and FIFOs enabled (FCR[0] set to one), this bit is set whenever the Transmitter Shift Register and the FIFO are both empty. If in non-FIFO mode or FIFOs are disabled, this bit is set whenever the Transmitter Holding Register and the Transmitter Shift Register are both empty. Reset Value: 0x1
5	0x1 RO	**THRE:** Transmit Holding Register Empty bit. If THRE_MODE_USER == Disabled or THRE mode is disabled (IER[7] set to zero) and regardless of FIFO's being implemented/enabled or not, this bit indicates that the THR or TX FIFO is empty. This bit is set whenever data is transferred from the THR or TX FIFO to the transmitter shift register and no new data has been written to the THR or TX FIFO. This also causes a THRE Interrupt to occur, if the THRE Interrupt is enabled. If THRE_MODE_USER == Enabled AND FIFO_MODE != NONE and both modes are active (IER[7] set to one and FCR[0] set to one respectively), the functionality is switched to indicate the transmitter FIFO is full, and no longer controls THRE interrupts, which are then controlled by the FCR[5:4] threshold setting. For more details, see Programmable THRE Interrupt on page 40. Reset Value: 0x1
4	0x0 RO	**BI:** Break Interrupt bit. This is used to indicate the detection of a break sequence on the serial input data. If in UART mode (SIR_MODE == Disabled), it is set whenever the serial input, sin, is held in a logic '0' state for longer than the sum of start time + data bits + parity + stop bits. If in infrared mode (SIR_MODE == Enabled), it is set whenever the serial input, sir_in, is continuously pulsed to logic '0' for longer than the sum of start time + data bits + parity + stop bits. A break condition on serial input causes one and only one character, consisting of all zeros, to be received by the UART. In the FIFO mode, the character associated with the break condition is carried through the FIFO and is revealed when the character is at the top of the FIFO. Reading the LSR clears the BI bit. In the non-FIFO mode, the BI indication occurs immediately and persists until the LSR is read. Reset Value: 0x0
3	0x0 RO	**FE:** Framing Error bit. This is used to indicate the occurrence of a framing error in the receiver. A framing error occurs when the receiver does not detect a valid STOP bit in the received data. In the FIFO mode, since the framing error is associated with a character received, it is revealed when the character with the framing error is at the top of the FIFO. When a framing error occurs, the UART tries to resynchronize. It does this by assuming that the error was due to the start bit of the next character and then continues receiving the other bit i.e. data, and/or parity and stop. It should be noted that the Framing Error (FE) bit (LSR[3]) is set if a break interrupt has occurred, as indicated by Break Interrupt (BI) bit (LSR[4]). 0 = no framing error 1 = framing error Reading the LSR clears the FE bit. Reset Value: 0x0
2	0x0 RO	**PE:** Parity Error bit. This is used to indicate the occurrence of a parity error in the receiver if the Parity Enable (PEN) bit (LCR[3]) is set. In the FIFO mode, since the parity error is associated with a character received, it is revealed when the character with the parity error arrives at the top of the FIFO. It should be noted that the Parity Error (PE) bit (LSR[2]) is set if a break interrupt has occurred, as indicated by Break Interrupt (BI) bit (LSR[4]). 0 = no parity error 1 = parity error Reading the LSR clears the PE bit. Reset Value: 0x0

Bit Range	Default & Access	Field Name (ID): Description
1	0x0 RO	**OE:** Overrun error bit. This is used to indicate the occurrence of an overrun error. This occurs if a new data character was received before the previous data was read. In the non-FIFO mode, the OE bit is set when a new character arrives in the receiver before the previous character was read from the RBR. When this happens, the data in the RBR is overwritten. In the FIFO mode, an overrun error occurs when the FIFO is full and a new character arrives at the receiver. The data in the FIFO is retained and the data in the receive shift register is lost. 0 = no overrun error 1 = overrun error Reading the LSR clears the OE bit. Reset Value: 0x0
0	0x0 RO	**DR:** Data Ready bit. This is used to indicate that the receiver contains at least one character in the RBR or the receiver FIFO. 0 = no data ready 1 = data ready This bit is cleared when the RBR is read in non-FIFO mode, or when the receiver FIFO is empty, in FIFO mode. Reset Value: 0x0

Reset Value: 0x0
3	0x0 RO	**DDCD:** Delta Data Carrier Detect. This is used to indicate that the modem control line dcd_n has changed since the last time the MSR was read. 0 = no change on dcd_n since last read of MSR 1 = change on dcd_n since last read of MSR Reading the MSR clears the DDCD bit. In Loopback Mode (MCR[4] = 1), DDCD reflects changes on MCR[3] (Out2). Note, if the DDCD bit is not set and the dcd_n signal is asserted (low) and a reset occurs (software or otherwise), then the DDCD bit is set when the reset is removed if the dcd_n signal remains asserted. Reset Value: 0x0
2	0x0 RO	**TERI:** Trailing Edge of Ring Indicator. This is used to indicate that a change on the input ri_n (from an active-low to an inactive-high state) has occurred since the last time the MSR was read. 0 = no change on ri_n since last read of MSR 1 = change on ri_n since last read of MSR Reading the MSR clears the TERI bit. In Loopback Mode (MCR[4] = 1), DDSR reflects changes on MCR[0] (DTR). Note, if the DDSR bit is not set and the dsr_n signal is asserted (low) and a reset occurs (software or otherwise), then the DDSR bit is set when the reset is removed if the dsr_n signal remains asserted. Reset Value: 0x0
0	0x0 RO	**DCTS:** Delta Clear to Send. This is used to indicate that the modem control line cts_n has changed since the last time the MSR was read. 0 = no change on cts_n since last read of MSR 1 = change on cts_n since last read of MSR Reading the MSR clears the DCTS bit. In Loopback Mode (MCR[4] = 1), DCTS reflects changes on MCR[1] (RTS). Note, if the DCTS bit is not set and the cts_n signal is asserted (low) and a reset occurs (software or otherwise), then the DCTS bit is set when the reset is removed if the cts_n signal remains asserted. Bit Range	Default & Access	Field Name (ID): Description
9	0x0 RW	**RFFE:** Receive FIFO Framing Error. These bits are only valid when FIFO access mode is enabled (FAR[0] is set to one). When FIFOs are implemented and enabled, this bit is used to write framing error detection information to the receive FIFO. When FIFOs are not implemented or not enabled, this bit is used to write framing error detection information to the RBR. Reset Value: 0x0
8	0x0 RW	**RFPE:** Receive FIFO Parity Error. These bits are only valid when FIFO access mode is enabled (FAR[0] is set to one). When FIFOs are implemented and enabled, this bit is used to write parity error detection information to the receive FIFO. When FIFOs are not implemented or not enabled, this bit is used to write parity error detection information to the RBR. Reset Value: 0x0
7:0	0x0 RW	**RFWD:** Receive FIFO Write Data. These bits are only valid when FIFO access mode is enabled (FAR[0] is set to one). When FIFOs are implemented and enabled, the data that is written to the RFWD is pushed into the receive FIFO. Each consecutive write pushes the new data to the next write location in the receive FIFO. When FIFOs are not implemented or not enabled, the data that is written to the RFWD is pushed into the RBR. Reset Value: 0x0

Offset: [BAR] + 7Ch

BAR Type: PCI Configuration Register (Size: 32 bits)
BAR Reference: [B:0, D:30, F:3] + 10h

Default: 00000006h

Bit Range	Default & Access	Field Name (ID): Description
31:5	0x0 RO	**RSVD0:** Reserved
4	0x0 RO	**RFF:** Receive FIFO Full. This bit is only valid when FIFO_STAT == YES. This is used to indicate that the receive FIFO is completely full. 0 = Receive FIFO not full 1 = Receive FIFO Full This bit is cleared when the RX FIFO is no longer full. Reset Value: 0x0
3	0x0 RO	**RFNE:** Receive FIFO Not Empty. This bit is only valid when FIFO_STAT == YES. This is used to indicate that the receive FIFO contains one or more entries. 0 = Receive FIFO is empty 1 = Receive FIFO is not empty This bit is cleared when the RX FIFO is empty. Reset Value: 0x0

Bit Range	Default & Access	Field Name (ID): Description
2	0x1 RO	**TFE:** Transmit FIFO Empty. This bit is only valid when FIFO_STAT == YES. This is used to indicate that the transmit FIFO is completely empty. 0 = Transmit FIFO is not empty 1 = Transmit FIFO is empty This bit is cleared when the TX FIFO is no longer empty. Reset Value: 0x1
1	0x1 RO	**TFNF:** Transmit FIFO Not Full. This bit is only valid when FIFO_STAT == YES. This is used to indicate that the transmit FIFO in not full. 0 = Transmit FIFO is full 1 = Transmit FIFO is not full This bit is cleared when the TX FIFO is full. Reset Value: 0x1
0	0x0 RO	**BUSY:** UART Busy. This bit is valid only when UART_16550_COMPATIBLE == NO and indicates that a serial transfer is in progress, ; when cleared, indicates that the DW_apb_uart is idle or inactive. 0 = DW_apb_uart is idle or inactive 1 = DW_apb_uart is busy (actively transferring data) NOTE: It is possible for the UART Busy bit to be cleared even though a new character may have been sent from another device. That is, if the DW_apb_uart has no data in THR and RBR and there is no transmission in progress and a start bit of a new character has just reached the DW_apb_uart. This is due to the fact that a valid start is not seen until the middle of the bit period and this duration is dependent on the baud divisor that has been programmed. If a second system clock has been implemented (CLOCK_MODE == Enabled), the assertion of this bit is also delayed by several cycles of the slower clock. Reset Value: 0x0

31:3	0x0 RO	**RSVD0:** Reserved

Bit Range	Default & Access	Field Name (ID): Description
2	0x0 RW	**XFR:** XMIT FIFO Reset. This is a shadow register for the XMIT FIFO Reset bit (FCR[2]). This can be used to remove the burden on software having to store previously written FCR values (which are pretty static) just to reset the transmit FIFO. This resets the control portion of the transmit FIFO and treats the FIFO as empty. This also de-asserts the DMA TX request and single signals when additional DMA handshaking signals are selected (DMA_EXTRA == YES). Note that this bit is 'self-clearing'. It is not necessary to clear this bit. Reset Value: 0x0 Dependencies: Writes have no effect when FIFO_MODE == None.
1	0x0 RW	**RFR:** RCVR FIFO Reset. This is a shadow register for the RCVR FIFO Reset bit (FCR[1]). This can be used to remove the burden on software having to store previously written FCR values (which are pretty static) just to reset the receive FIFO This resets the control portion of the receive FIFO and treats the FIFO as empty. This also de-asserts the DMA RX request and single signals when additional DMA handshaking signals are selected (DMA_EXTRA == YES). Note that this bit is 'self-clearing'. It is not necessary to clear this bit. Reset Value: 0x0 Dependencies: Writes have no effect when FIFO_MODE == None.

Bit Range	Default & Access	Field Name (ID): Description
0	0x0 RW	**srts:** Shadow Request to Send. This is a shadow register for the RTS bit (MCR[1]), this can be used to remove the burden of having to performing a read-modify-write on the MCR. This is used to directly control the Request to Send (rts_n) output. The Request To Send (rts_n) output is used to inform the modem or data set that the DW_apb_uart is ready to exchange data. When Auto RTS Flow Control is not enabled (MCR[5] = 0), the rts_n signal is set low by programming MCR[1] (RTS) to a high. In Auto Flow Control, AFCE_MODE == Enabled and active (MCR[5] = 1) and FIFOs enable (FCR[0] = 1), the rts_n output is controlled in the same way, but is also gated with the receiver FIFO threshold trigger (rts_n is inactive high when above the threshold). Note that in Loopback mode (MCR[4] = 1), the rts_n output is held inactive-high while the value of this location is internally looped back to an input. Reset Value: 0x0

9.26.33 Shadow Break Control Register (SBCR)—Offset 90h

Shadow Break Control Bit. This is a shadow register for the Break bit (LCR[6]), this can be used to remove the burden of having to performing a read modify write on the LCR. This is used to cause a break condition to be transmitted to the receiving device. If set to one the serial output is forced to the spacing (logic 0) state. When not in Loopback Mode, as determined by MCR[4], the sout line is forced low until the Break bit is cleared. If SIR_MODE == Enabled and active (MCR[6] = 1) the sir_out_n line is continuously pulsed. When in Loopback Mode, the break condition is internally looped back to the receiver. Reset Value: 0x0

This bit must be cleared after initial baud rate setup in order to access other registers. Reset Value: 0x0
6	0x0 RW	**Break:** Break Control Bit.This is used to cause a break condition to be transmitted to the receiving device. If set to one the serial output is forced to the spacing (logic 0) state. When not in Loopback Mode, as determined by MCR[4], the sout line is forced low until the Break bit is cleared. If SIR_MODE == Enabled and active (MCR[6] set to one) the sir_out_n line is continuously pulsed. When in Loopback Mode, the break condition is internally looped back to the receiver and the sir_out_n line is forced low. Reset Value: 0x0
5	0x0 RO	**RSVD1:** Reserved
4	0x0 RW	**EPS:** Even Parity Select. If UART_16550_COMPATIBLE == NO, then writeable only when UART is not busy (USR[0] is zero); otherwise always writable, always readable. This is used to select between even and odd parity, when parity is enabled (PEN set to one). If set to one, an even number of logic 1s is transmitted or checked. If set to zero, an odd number of logic 1s is transmitted or checked. Reset Value: 0x0
3	0x0 RW	**PEN:** Parity Enable. If UART_16550_COMPATIBLE == NO, then writeable only when UART is not busy (USR[0] is zero); otherwise always writable, always readable. This bit is used to enable and disable parity generation and detection in transmitted and received serial character respectively. 0 = parity disabled 1 = parity enabled Reset Value: 0x0
2	0x0 RW	**STOP:** Number of stop bits. If UART_16550_COMPATIBLE == NO, then writeable only when UART is not busy (USR[0] is zero); otherwise always writable, always readable. This is used to select the number of stop bits per character that the peripheral transmits and receives. If set to zero, one stop bit is transmitted in the serial data. If set to one and the data bits are set to 5 (LCR[1:0] set to zero) one and a half stop bits is transmitted. Otherwise, two stop bits are transmitted. Note that regardless of the number of stop bits selected, the receiver checks only the first stop bit. 0 = 1 stop bit 1 = 1.5 stop bits when DLS (LCR[1:0]) is zero, else 2 stop bit Reset Value: 0x0
1:0	0x0 RW	**DLS:** Data Length Select. If UART_16550_COMPATIBLE == NO, then writeable only when UART is not busy (USR[0] is zero); otherwise always writable, always readable. This is used to select the number of data bits per character that the peripheral transmits and receives. The number of bit that may be selected areas follows: 00 = 5 bits 01 = 6 bits 10 = 7 bits 11 = 8 bits Reset Value: 0x0

Modem Control Register

Access Method

Type: Memory Mapped I/O Register (Size: 32 bits)

Offset: [BAR] + 10h

BAR Type: PCI Configuration Register (Size: 32 bits)
BAR Reference: [B:0, D:30, F:4] + 10h

Default: 00000000h

Bit Range	Default & Access	Field Name (ID): Description
31:6	0x0 RO	**RSVD0:** Reserved
5	0x0 RW	**AFCE:** Auto Flow Control Enable. Writeable only when AFCE_MODE == Enabled, always readable. When FIFOs are enabled and the Auto Flow Control Enable (AFCE) bit is set, Auto Flow Control features are enabled as described in Auto Flow Control on page 37. 0 = Auto Flow Control Mode disabled 1 = Auto Flow Control Mode enabled Reset Value: 0x0
4	0x0 RW	**LoopBack:** LoopBack Bit. This is used to put the UART into a diagnostic mode for test purposes. If operating in UART mode (SIR_MODE != Enabled or not active, MCR[6] set to zero), data on the sout line is held high, while serial data output is looped back to the sin line, internally. In this mode all the interrupts are fully functional. Also, in loopback mode, the modem control inputs (dsr_n, cts_n, ri_n, dcd_n) are disconnected and the modem control outputs (dtr_n, rts_n, out1_n, out2_n) are looped back to the inputs, internally. If operating in infrared mode (SIR_MODE == Enabled AND active, MCR[6] set to one), data on the sir_out_n line is held low, while serial data output is inverted and looped back to the sir_in line. Reset Value: 0x0
3	0x0 RW	**OUT2:** OUT2. This is used to directly control the user-designated Output2 (out2_n) output. The value written to this location is inverted and driven out on out2_n, that is: 0 = out2_n de-asserted (logic 1) 1 = out2_n asserted (logic 0) Note that in Loopback mode (MCR[4] set to one), the out2_n output is held inactive high while the value of this location is internally looped back to an input. Reset Value: 0x0
2	0x0 RW	**OUT1:** OUT1. This is used to directly control the user-designated Output1 (out1_n) output. The value written to this location is inverted and driven out on out1_n, that is: 0 = out1_n de-asserted (logic 1) 1 = out1_n asserted (logic 0) Note that in Loopback mode (MCR[4] set to one), the out1_n output is held inactive high while the value of this location is internally looped back to an input. Reset Value: 0x0

Bit Range	Default & Access	Field Name (ID): Description
1	0x0 RW	**RTS:** Request to Send. This is used to directly control the Request to Send (rts_n) output. The Request To Send (rts_n) output is used to inform the modem or data set that the UART is ready to exchange data. When Auto RTS Flow Control is not enabled (MCR[5] set to zero), the rts_n signal is set low by programming MCR[1] (RTS) to a high.In Auto Flow Control, AFCE_MODE == Enabled and active (MCR[5] set to one) and FIFOs enable (FCR[0] set to one), the rts_n output is controlled in the same way, but is also gated with the receiver FIFO threshold trigger (rts_n is inactive high when above the threshold). The rts_n signal is de-asserted when MCR[1] is set low. Note that in Loopback mode (MCR[4] set to one), the rts_n output is held inactive high while the value of this location is internally looped back to an input. Reset Value: 0x0
0	0x0 RW	**DTR:** Data Terminal Ready. This is used to directly control the Data Terminal Ready (dtr_n) output. The value written to this location is inverted and driven out on dtr_n, that is: 0 = dtr_n de-asserted (logic 1) 1 = dtr_n asserted (logic 0) The Data Terminal Ready output is used to inform the modem or data set that the UART is ready to establish communications. Note that in Loopback mode (MCR[4] set to one), the dtr_n output is held inactive high while the value of this location is internally looped back to an input. Reset Value: 0x0

BAR Type: PCI Configuration Register (Size: 32 bits)
BAR Reference: [B:0, D:30, F:4] + 10h

Default: 00000060h

Bit Range	Default & Access	Field Name (ID): Description
31:8	0x0 RO	**RSVD0:** Reserved
7	0x0 RO	**RFE:** Receiver FIFO Error bit. This bit is only relevant when FIFO_MODE != NONE AND FIFOs are enabled (FCR[0] set to one). This is used to indicate if there is at least one parity error, framing error, or break indication in the FIFO. 0 = no error in RX FIFO 1 = error in RX FIFO This bit is cleared when the LSR is read and the character with the error is at the top of the receiver FIFO and there are no subsequent errors in the FIFO. Reset Value: 0x0

Bit Range	Default & Access	Field Name (ID): Description
6	0x1 RO	**TEMT:** Transmitter Empty bit. If in FIFO mode (FIFO_MODE != NONE) and FIFOs enabled (FCR[0] set to one), this bit is set whenever the Transmitter Shift Register and the FIFO are both empty. If in non-FIFO mode or FIFOs are disabled, this bit is set whenever the Transmitter Holding Register and the Transmitter Shift Register are both empty. Reset Value: 0x1
5	0x1 RO	**THRE:** Transmit Holding Register Empty bit. If THRE_MODE_USER == Disabled or THRE mode is disabled (IER[7] set to zero) and regardless of FIFO's being implemented/enabled or not, this bit indicates that the THR or TX FIFO is empty. This bit is set whenever data is transferred from the THR or TX FIFO to the transmitter shift register and no new data has been written to the THR or TX FIFO. This also causes a THRE Interrupt to occur, if the THRE Interrupt is enabled. If THRE_MODE_USER == Enabled AND FIFO_MODE != NONE and both modes are active (IER[7] set to one and FCR[0] set to one respectively), the functionality is switched to indicate the transmitter FIFO is full, and no longer controls THRE interrupts, which are then controlled by the FCR[5:4] threshold setting. For more details, see Programmable THRE Interrupt on page 40. Reset Value: 0x1
4	0x0 RO	**BI:** Break Interrupt bit. This is used to indicate the detection of a break sequence on the serial input data. If in UART mode (SIR_MODE == Disabled), it is set whenever the serial input, sin, is held in a logic '0' state for longer than the sum of start time + data bits + parity + stop bits. If in infrared mode (SIR_MODE == Enabled), it is set whenever the serial input, sir_in, is continuously pulsed to logic '0' for longer than the sum of start time + data bits + parity + stop bits. A break condition on serial input causes one and only one character, consisting of all zeros, to be received by the UART. In the FIFO mode, the character associated with the break condition is carried through the FIFO and is revealed when the character is at the top of the FIFO. Reading the LSR clears the BI bit. In the non-FIFO mode, the BI indication occurs immediately and persists until the LSR is read. Reset Value: 0x0
3	0x0 RO	**FE:** Framing Error bit. This is used to indicate the occurrence of a framing error in the receiver. A framing error occurs when the receiver does not detect a valid STOP bit in the received data. In the FIFO mode, since the framing error is associated with a character received, it is revealed when the character with the framing error is at the top of the FIFO. When a framing error occurs, the UART tries to resynchronize. It does this by assuming that the error was due to the start bit of the next character and then continues receiving the other bit i.e. data, and/or parity and stop. It should be noted that the Framing Error (FE) bit (LSR[3]) is set if a break interrupt has occurred, as indicated by Break Interrupt (BI) bit (LSR[4]). 0 = no framing error 1 = framing error Reading the LSR clears the FE bit. Reset Value: 0x0
2	0x0 RO	**PE:** Parity Error bit. This is used to indicate the occurrence of a parity error in the receiver if the Parity Enable (PEN) bit (LCR[3]) is set. In the FIFO mode, since the parity error is associated with a character received, it is revealed when the character with the parity error arrives at the top of the FIFO. It should be noted that the Parity Error (PE) bit (LSR[2]) is set if a break interrupt has occurred, as indicated by Break Interrupt (BI) bit (LSR[4]). 0 = no parity error 1 = parity error Reading the LSR clears the PE bit. Reset Value: 0x0

Bit Range	Default & Access	Field Name (ID): Description
1	0x0 RO	**OE:** Overrun error bit. This is used to indicate the occurrence of an overrun error. This occurs if a new data character was received before the previous data was read. In the non-FIFO mode, the OE bit is set when a new character arrives in the receiver before the previous character was read from the RBR. When this happens, the data in the RBR is overwritten. In the FIFO mode, an overrun error occurs when the FIFO is full and a new character arrives at the receiver. The data in the FIFO is retained and the data in the receive shift register is lost. 0 = no overrun error 1 = overrun error Reading the LSR clears the OE bit. Reset Value: 0x0
0	0x0 RO	**DR:** Data Ready bit. This is used to indicate that the receiver contains at least one character in the RBR or the receiver FIFO. 0 = no data ready 1 = data ready This bit is cleared when the RBR is read in non-FIFO mode, or when the receiver FIFO is empty, in FIFO mode. Reset Value: 0x0

Reset Value: 0x0
6	0x0 RO	**RI:** Ring Indicator. This is used to indicate the current state of the modem control line ri_n. This bit is the complement of ri_n. 5	0x0 RO	**DSR:** Data Set Ready. This is used to indicate the current state of the modem control line dsr_n. This bit is the complement of dsr_n. When the Data Set Ready input (dsr_n) is asserted it is an indication that the modem or data set is ready to establish communications with the DW_apb_uart. 0 = dsr_n input is de-asserted (logic 1) 1 = dsr_n input is asserted (logic 0) In Loopback Mode (MCR[4] set to one), DSR is the same as MCR[0] (DTR). Reset Value: 0x0
4	0x0 RO	**CTS:** Clear to Send. This is used to indicate the current state of the modem control line cts_n. This bit is the complement of cts_n. When the Clear to Send input (cts_n) is asserted it is an indication that the modem or data set is ready to exchange data with the DW_apb_uart. 0 = cts_n input is de-asserted (logic 1) 1 = cts_n input is asserted (logic 0) In Loopback Mode (MCR[4] = 1), CTS is the same as MCR[1] (RTS). Reset Value: 0x0
3	0x0 RO	**DDCD:** Delta Data Carrier Detect. This is used to indicate that the modem control line dcd_n has changed since the last time the MSR was read. 0 = no change on dcd_n since last read of MSR 1 = change on dcd_n since last read of MSR Reading the MSR clears the DDCD bit. In Loopback Mode (MCR[4] = 1), DDCD reflects changes on MCR[3] (Out2). Note, if the DDCD bit is not set and the dcd_n signal is asserted (low) and a reset occurs (software or otherwise), then the DDCD bit is set when the reset is removed if the dcd_n signal remains asserted. Reset Value: 0x0
2	0x0 RO	**TERI:** Trailing Edge of Ring Indicator. This is used to indicate that a change on the input ri_n (from an active-low to an inactive-high state) has occurred since the last time the MSR was read. 0 = no change on ri_n since last read of MSR 1 = change on ri_n since last read of MSR Reading the MSR clears the TERI bit. In Loopback Mode (MCR[4] = 1), TERI reflects when MCR[2] (Out1) has changed state from a high to a low. Reset Value: 0x0
1	0x0 RO	**DDSR:** Delta Data Set Ready. This is used to indicate that the modem control line dsr_n has changed since the last time the MSR was read. 0 = no change on dsr_n since last read of MSR 1 = change on dsr_n since last read of MSR Reading the MSR clears the DDSR bit. In Loopback Mode (MCR[4] = 1), DDSR reflects changes on MCR[0] (DTR). Note, if the DDSR bit is not set and the dsr_n signal is asserted (low) and a reset occurs (software or otherwise), then the DDSR bit is set when the reset is removed if the dsr_n signal remains asserted. Reset Value: 0x0
0	0x0 RO	**DCTS:** Delta Clear to Send. This is used to indicate that the modem control line cts_n has changed since the last time the MSR was read. 0 = no change on cts_n since last read of MSR 1 = change on cts_n since last read of MSR Reading the MSR clears the DCTS bit. In Loopback Mode (MCR[4] = 1), DCTS reflects changes on MCR[1] (RTS). When Auto RTS Flow Control is not enabled (MCR[5] = 0), the rts_n signal is set low by programming MCR[1] (RTS) to a high. In Auto Flow Control, AFCE_MODE == Enabled and active (MCR[5] = 1) and FIFOs enable (FCR[0] = 1), the rts_n output is controlled in the same way, but is also gated with the receiver FIFO threshold trigger (rts_n is inactive high when above the threshold). When not in Loopback Mode, as determined by MCR[4], the sout line is forced low until the Break bit is cleared. 1:0	0x0 RW	**srt:** Shadow RCVR Trigger. This is a shadow register for the RCVR trigger bits (FCR[7:6]). This can be used to remove the burden of having to store the previously written value to the FCR in memory and having to mask this value so that only the RCVR trigger bit gets updated. This is used to select the trigger level in the receiver FIFO at which the Received Data Available Interrupt is generated. It also determines when the dma_rx_req_n signal is asserted when DMA Mode (FCR[3]) = 1. The following trigger levels are supported: 00 = 1 character in the FIFO 01 = FIFO full 10 = FIFO full 11 = FIFO 2 less than full Reset Value: 0x0

Shadow TX Empty Trigger. This is a shadow register for the TX empty trigger bits (FCR[5:4]). This can be used to remove the burden of having to store the previously written value to the FCR in memory and having to mask this value so that only the TX empty trigger bit gets updated. This is used to select the empty threshold level at which the THRE Interrupts are generated when the mode is active. The following

trigger levels are supported: 00 = FIFO empty 01 = 2 characters in the FIFO 10 = FIFO full 11 = FIFO full Reset Value: 0x0 Dependencies: Writes have no effect when THRE_MODE_USER == Disabled.

10.2.1 PRSTS - Power and Reset Status (PRSTS)—Offset 0h

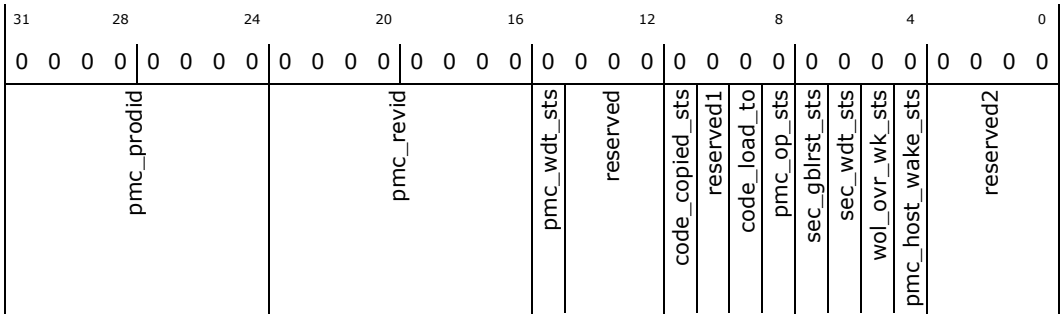
Bits in this register only need to be valid for reading when the Main power well is up. However, since some of the events may initially be detected while the Main power well is down, they are marked as suspend well bits. All suspend well bits in this register are reset by global reset#.

Access Method

Type: Memory Mapped I/O Register (Size: 32 bits)

Offset: [PMC_BASE_ADDRESS] + 0h

Default: 00000000h



Bit Range	Default & Access	Field Name (ID): Description
31:24	0x0 RO	**Power Management Controller Product ID (PMC_PRODID) (pmc_prodid):** This field communicates the Product Family of the power management functionality
23:16	0x0 RO	**Power Management Controller Revision ID (PMC_REVID) (pmc_revid):** This field communicates the implementation revision of the power management functionality.
15	0x0 RW/1C	**PMC Watchdog Timer Status (PMC_WDT_STS) (pmc_wdt_sts):** This bit will be set to '1' when the PMC Watch Dog Timer triggers a reset. It will be cleared by a write of '1' by software.
14:12	0x0 RO	**reserved:** Reserved.
11	0x0 RO	**Code Copied Over Status (CODE_COPIED_STS) (code_copied_sts):** The SOC sets this bit when PMC code is successfully authenticated and loaded from the flash
10	0x0 RO	**reserved (reserved1):** Reserved.
9	0x0 RO	**Code Load Timeout Status (CODE_LOAD_TO) (code_load_to):** The SOC sets this bit if the loading function fails to complete within a reasonable time limit. This bit remains valid after a PMC Code load is attempted until the next global reset
8	0x0 RO	**PMC Operational Status (PMC_OP_STS) (pmc_op_sts):** The SOC sets this bit when the PMC becomes operational after completing the Code Load. BIOS must wait for this bit to be set before performing resets or sleep events. This bit remains valid after a PMC Code load until the next global reset

Bit Range	Default & Access	Field Name (ID): Description
7	0x0 RW/1C	**SEC Watch Dog Timer Status (SEC_GBLRST_STS) (sec_gblrst_sts):** This bit will be set to '1' when the SEC FW triggers a reset. It will be cleared by a write of '1' by software.
6	0x0 RW/1C	**SEC Watch Dog Timer Status (SEC_WDT_STS) (sec_wdt_sts):** This bit will be set to '1' when the SEC Watch Dog Timer triggers a reset. It will be cleared by a write of '1' by software.
5	0x0 RW/1C	**Wake On LAN Override Wake Status (WOL_OVR_WK_STS) (wol_ovr_wk_sts):** This bit gets set when integrated LAN Signals a Power Management Event AND the system is in S5. BIOS can read this status bit to determine this wake source. Software clears this bit by writing a 1 to it.
4	0x0 RW/1C	**PMC_HOST_WAKE_STS (PMC_HOST_WAKE_STS) (pmc_host_wake_sts):** The SOC Power Management Controller sets this bit if it wakes the host for reasons other than typical host-visible wake events. This status bit provides information to BIOS that the PMC caused the wake.

10.2.3 PM_CFG - Power Management Configuration (PMC_CFG)—Offset 8h

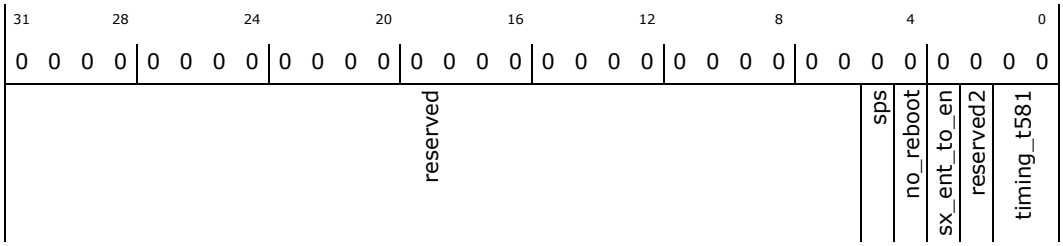
This register contains misc. fields used to configure the SOC's power management behavior.

Access Method

Type: Memory Mapped I/O Register (Size: 32 bits)

Offset: [PMC_BASE_ADDRESS] + 8h

Default: 00000000h



Bit Range	Default & Access	Field Name (ID): Description
31:6	0x0 RO	**reserved:** Reserved.
5	0x0 RW	**Shutdown Policy Select (SPS) (sps):** When cleared (default) the SOC will drive INIT# in response to the shutdown Message. When set to 1, SOC will treat the shutdown message similar to receiving a CF9h I/O write, and will drive PMU_PLTRST active. Note: This register is reset any time PMU_PLTRST asserts.
4	0x0 RW	**No Reboot (NO_REBOOT) (no_reboot):** This bit is set when the No Reboot strap is sampled high on COREPWROK. This bit may be set or cleared by software if the strap is sampled low but may not override the strap when it indicates No Reboot. When set, the TCO timer will count down and generate the SMI# on the first timeout, but will not reboot on the second timeout.
3	0x0 RW	**S1/3/4/5 Entry Timeout Enable (SX_ENT_TO_EN) (sx_ent_to_en):** This policy bit determines whether the SOC will apply a timeout to the S1/S3/S4/S5 entry flow. If this timeout is enabled and the entry flow appears to be hung, the SOC will trigger a straight-to-S5 global reset. Encodings: 0: Timeout disabled (default) 1: Timeout enabled reset_type=RSMRST_B
2	0x0 RO	**reserved (reserved2):** Reserved.
1:0	0x0 RW	**Timing t581 (TIMING_T581) (timing_t581):** This field configures the t581 timing involved in the power down flow (CPU Power Good indication inactive to PLL Enable inactive). Encodings (all min timings): 00: 10 us (default) 01: 100 us 10: 1 ms 11: 10 ms reset_type=Resume Well Reset#

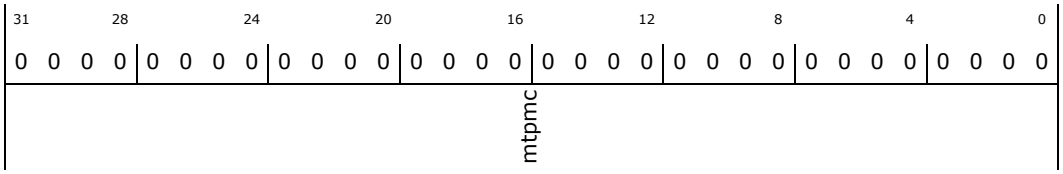
10.2.4 MTPMC - Message to PMC (MTPMC)—Offset 10h

Access Method

Type: Memory Mapped I/O Register (Size: 32 bits)

Offset: [PMC_BASE_ADDRESS] + 10h

Default: 00000000h



Bit Range	Default & Access	Field Name (ID): Description
31:0	0x0 RW	**Message to PMC (MTPMC) (mtpmc):** A write to any of the bytes in this field causes an interrupt to the PMC. The PMC can read the contents of this register. The host must wait until the PMC has taken action on the previous write to MTPMC, as indicated by the PMC Message Full Status (PMC_MSG_1_FULL_STS) bit being cleared, before initiating another write to the MTPMC register. In the case of a message that involves a response from the PMC (such as a PMC XRAM read), the host must also consume any data returned by the PMC in the Message from PMC register (MFPMC) before initiating another message

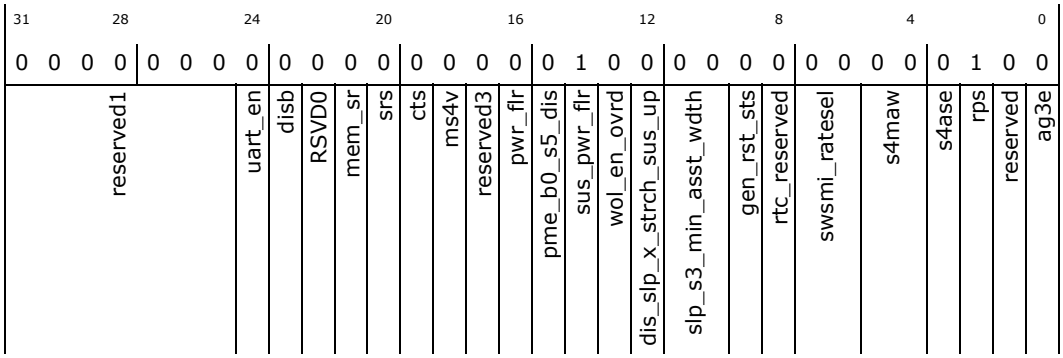
10.2.8 General PM Configuration 1 (GEN_PMCON1)—Offset 20h

Access Method

Type: Memory Mapped I/O Register (Size: 32 bits)

Offset: [PMC_BASE_ADDRESS] + 20h

Default: 00004004h



Bit Range	Default & Access	Field Name (ID): Description
31:25	0x0 RO	**reserved1:** Reserved.
24	0x0 RW	**UART Enable (UART_EN) (uart_en):** When set, PMC enables UART debug port
23	0x0 RW	**DRAM Initialization Scratchpad Bit (DISB) (disb):** This bit does not effect hardware functionality in any way. It is provided as a scratchpad bit that is maintained through main power well resets and CF9h-initiated resets. BIOS is expected to set this bit prior to starting the DRAM initialization sequence and to clear this bit after completing the DRAM initialization sequence. BIOS can detect that a DRAM initialization sequence was interrupted by a reset by reading this bit during the boot sequence. If the bit is 1, then the DRAM initialization was interrupted. This bit is reset by the assertion of the RSMRST_B pin.
22	0x0 RO	**RSVD0:** Reserved
21	0x0 RO	**Memory Placed in Self-Refresh (MEM_SR) (mem_sr):** This bit will be set to 1 if DRAM should have remained powered and held in Self-Refresh through the last power state transition (i.e. the last time the system left S0). The scenarios where this should be the case are: - successful S3 entry and exit - successful Host partition reset without power cycle This bit will be cleared whenever the SOC begins a transition out of S0. Note: This bit should not be consulted upon wake from S1, as that state does not involve the same type of handshake or placing memory into Self-Refresh. It is assumed that software is already aware that memory context is not impacted by S1 and therefore does not need to check this bit. reset_type=global reset
20	0x0 RW/1C	**System Reset Status (SRS) (srs):** SOC sets this bit when the PMU_RESETBUTTON_B# button is pressed. BIOS is expected to read this bit and clear it if it is set. This bit is also reset by RSMRST_B and CF9h resets. reset_type=Resume Well Reset#
19	0x0 RW/1C	**CPU Thermal Trip Status (CTS) (cts):** This bit is set when the SOC thermal trip active while the system is in a valid state to honor the pin. This bit is also reset by RSMRST_B and CF9h resets. It is not reset by the shutdown and reboot associated with the thermal trip event. reset_type=Resume Well Reset#

Bit Range	Default & Access	Field Name (ID): Description
18	0x0 RW/1C	**Minimum PMU_SLP_S4_B Assertion Width Violation Status (MS4V) (ms4v):** Hardware sets this bit when the PMU_SLP_S4_B assertion width is less than the time programmed in the PMU_SLP_S4_B Minimum Assertion Width field. The SOC begins the timer when PMU_SLP_S4_B pin is asserted during S4/S5 entry, or when the RSMRST_B input is deasserted during SUS well power-up. The status bit is cleared by software writing a 1 to the bit. Note that this bit is functional regardless of the value in the PMU_SLP_S4_B Assertion Stretch Enable and the Disable-SLP_X-Stretching-After-SUS-Power-Failure bits. This bit is reset by the assertion of the RSMRST_B pin, but can be set in some cases before the default value is readable. reset_type=RSMRST_B
17	0x0 RO	**reserved3:** Reserved.
16	0x0 RW/1C	**COREPWROK Failure (PWR_FLR) (pwr_flr):** Intel SOC sets this bit any time COREPWROK goes low if the system was in an S0 or S1 state. The bit will be cleared only by software writing a 1 back to the bit or by SUS well power loss. reset_type=global reset
15	0x0 RW	**PME B0 S5 Disable (PME_B0_S5_DIS) (pme_b0_s5_dis):** When set to '1', this bit blocks wake events from PME_B0_STS in S5, regardless of the state of PME_B0_EN. When cleared (default), wake events from PME_B0_STS are allowed in S5 if PME_B0_EN = '1'. Wakes from power states other than S5 are not affected by this policy bit. The net effect of setting PME_B0_S5_DIS = '1' is described by the truth table below: Y = Wake N = Don't wake B0 = PME_B0_EN OV = WOL Enable Override B0/OV | S1/S3/S4 | S5 00 | N | N 01 | N | Y (LAN only) 11 | Y (all PME B0 sources) | Y (LAN only) 10 | Y (all PME B0 sources) | N This bit is cleared by the SRTCRST_B pin. reset_type=SRTCRST_B
14	0x1 RW/1C	**SUS Well Power Failure (SUS_PWR_FLR) (sus_pwr_flr):** This bit is set to '1' whenever SUS well power is lost, as indicated by RSMRST_B assertion. Software writes a 1 to this bit to clear it. This bit is in the SUS well, and defaults to '1' based on RSMRST_B assertion (not cleared by any type of reset). Implementation Note: RSMRST_B is an asynchronous set term to this bit. reset_type=RSMRST_B
13	0x0 RW	**WOL Enable Override (WOL_EN_OVRD) (wol_en_ovrd):** When this bit is set to 1, the integrated LAN is enabled to wake the system from S5 regardless of the value in the PME_B0_EN bit in the GPE0a_EN register. This allows the system BIOS to enable Wake-On-LAN regardless of the policies selected through the operating system. This bit is maintained in the RTC power well, therefore permitting WOL following a surprise power failure even in cases in which the system may have been running in S0 without the PME Enables set. (Note that the LAN NVRAM configuration must support WOL after SUS power loss.) When this bit is cleared to 0, the wake-on-LAN policies are determined by OS-visible bits. This bit has no effect on wakes from S1, S3, or S4. This bit is cleared by the SRTCRST_B pin reset_type=SRTCRST_B

Bit Range	Default & Access	Field Name (ID): Description
12	0x0 RW	**Disable SLP_X Stretching After SUS Well Power Up (DIS_SLP_X_STRCH_SUS_UP) (dis_slp_x_strch_sus_up):** When this bit is set to 1, all SLP_* pin stretching is disabled when powering up after a SUS well power loss. When this bit is left at 0, SLP_* stretching will be performed after SUS power failure as enabled in various other fields. Note that if this bit is a 0, SLP_* stretch timers start on SUS well power up (the SOC has no ability to count stretch time while the SUS well is powered down). Setting this bit can therefore prevent long delays after SUS power loss which may be common in mobile platforms and in manufacturing flow testing, while still allowing for the full power cycling during S3, S4 and S5 states. If the platform guarantees minimum SUS power down residence in other ways, an additional SOC-induced delay is not needed or wanted. This field is not writable when the SLP_Sx# Stretching Policy Lock-Down bit is set. This bit is cleared by the SRTCRST_B pin.
11:10	0x0 RW	**PMU_SLP_S3_B Minimum Assertion Width (SLP_S3_MIN_ASST_WDTH) (slp_s3_min_asst_wdth):** This 2-bit value indicates the minimum assertion width of the PMU_SLP_S3_B signal to guarantee that the Main power supplies have been fully power-cycled. This value may be modified per platform depending on power supply capacitance, board capacitance, power failure detection circuits, etc. Settings are: 00: 60 usec 01: 1 ms 10: 50 ms 11: 2 sec This field is not writable when the SLP_Sx# Stretching Policy Lock- Down bit is set. This bit is cleared by the RSMRST_B pin. reset_type=RSMRST_B
9	0x0 RW/1C	**General Reset Status (GEN_RST_STS) (gen_rst_sts):** This bit is set by hardware whenever PMU_PLTRST asserts for any reason other than going into a software-entered sleep state (via PM1_CNT.SLP_EN write). This bit is an optional tool to help BIOS determine when a reset might have collided with a wake from a valid sleep state. A possible usage model would be to consult and then write a '1' to clear this bit during the boot flow before determing what action to take based on reading PM1_STS.WAK_STS = '1'. If GEN_RST_STS = '1', the cold reset boot path could be followed rather than the resume path, regardless of the setting of WAK_STS. This bit does not affect SOC operation in any way, and can therefore be left set if BIOS chooses not to use it. This bit is set by global reset. reset_type=global reset
8	0x0 RW	**RTC_reserved (rtc_reserved):** reset_type=SRTCRST_B
7:6	0x0 RW	**SWSMI Rate Select (SWSMI_RATESEL) (swsmi_ratesel):** This 2-bit value indicates when the SWSMI timer will time out. Valid values are: 00 1.5ms +/- 0.6ms 01 16ms +/- 4ms 10 32ms +/- 4ms 11 64ms +/- 4ms These bits are not cleared by any type of reset except SRTCRST_B. Implementation Note: SWSMI is generated based on the internal free-running 1ms tick (to be accurate, it is 0.983ms/tick generated from 30ns * 2^15). Since the tick is free-running, the accuracy is within the following range. # of 0.983ms tick count SWSMI range 64ms SWSMI 62 -to- 63 60.946ms -to- 61.929ms 32ms SWSMI 31 -to- 32 30.473ms -to- 31.456ms 16ms SWSMI 15 -to- 16 14.745ms -to- 15.728ms 1.5ms SWSMI 1 -to- 2 0.983ms -to- 1.966ms reset_type=SRTCRST_B

Bit Range	Default & Access	Field Name (ID): Description
5:4	0x0 RW	**PMU_SLP_S4_B Minimum Assertion Width (S4MAW) (s4maw):** This 2-bit value indicates the minimum assertion width of the PMU_SLP_S4_B signal to guarantee that the DRAMs have been safely power-cycled. This value may be modified per platform depending on DRAM types, power supply capacitance, etc. Valid values are: - 11: 1 second - 10: 2 seconds - 01: 3 seconds - 00: 4 seconds This value is used in two ways: 1. If the PMU_SLP_S4_B assertion width is ever shorter than this time, a status bit is set for BIOS to read when S0 is entered 2. If enabled by bit 3 in this register, the hardware will prevent the PMU_SLP_S4_B signal from deasserting within this minimum time period after asserting. Note that the logic that measures this time is in the suspend power well. Therefore, when leaving a G3 state, the minimum time is measured from the deassertion of the internal suspend well reset (unless the Disable SLP_X Stretching After SUS Power Failure bit is set). This field is not writable when the SLP_Sx# Stretching Policy Lock-Down bit is set. SRTCRST_B forces this field to the conservative default state (00b). reset_type=SRTCRST_B
3	0x0 RW	**PMU_SLP_S4_B Assertion Stretch Enable (S4ASE) (s4ase):** When set to 1, the PMU_SLP_S4_B pin will minimally assert for the time specified in bits 5:4 of this register. This bit is provided so that all DIMMs in the system can deterministically detect a power-cycle event for proper initialization. Note that there are behavioral changes that may be noticeable to the end-user when this bit is set. Resume times from S4 and S5 and power-up times from G3 may be delayed by several seconds. Cases in which this feature may not be desirable and therefore keeping the bit cleared are: - A customer decides the user confusion due to the hardware delay is a bigger issue than the potential DRAM issue - A customer decides the software status bit solution is adequate - A different DRAM type is used or the platform provides an external solution to solve the power-cycling issue - Validation regressions are impacted by the delay (especially after RSMRST_B deassertion) - Avoid potential resume time WHQL violations This bit is not writable when the SLP_Sx# Stretching Policy Lock-Down bit is set. This bit is cleared by SRTCRST_B. reset_type=SRTCRST_B
2	0x1 RW	**RTC_PWR_STS (RPS) (rps):** Intel SOC will set this bit to 1 when RTEST_B indicates a weak or missing battery. The bit will remain set until the software clears it by writing a 0 back to this bit position. This bit is not cleared by any type of reset. reset_type=RTEST_B
1	0x0 RO	**reserved:** Reserved.
0	0x0 RW	**AFTERG3_EN (AG3E) (ag3e):** Determines what state to go to when power is reapplied after a power failure (G3 state). 0 = System will return to an S0 state (boot) after power is re-applied. 1 = System will return to the S5 state (except if it was in S4, in which case it will return to S4-like state). In the S5 state, the only enabled wake-up event is the Power Button or any enabled wake event that was preserved through the power failure. This bit is in the RTC well and is only cleared by SRTCRST_B assertion. reset_type=SRTCRST_B

10.2.18 ETR - Extended Test Mode Register (ETR)—Offset 48h

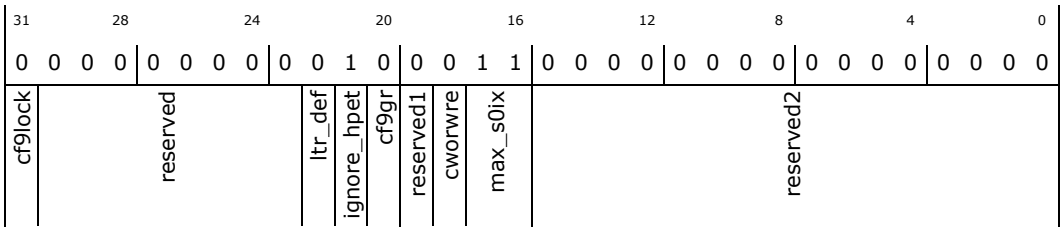
This register resides in the resume well. All bits except bit[23:16] are reset by internal Resume Well Reset. Bit[23:16] are reset by RSMRST_B only.

Access Method

Type: Memory Mapped I/O Register (Size: 32 bits)

Offset: [PMC_BASE_ADDRESS] + 48h

Default: 00230000h



Bit Range	Default & Access	Field Name (ID): Description
31	0x0 RW	**CF9h Lockdown (CF9LOCK) (cf9lock):** When set, this will lock the CF9h-Global-Reset bit. When set, this register locks itself. This register is reset by a CF9h reset.
30:23	0x0 RO	**reserved:** Reserved.

20	0x0 RW	**CF9h Global Reset (CF9GR) (cf9gr):** When this bit is set, a CF9h write of 6h or Eh will cause a Global Reset of the Host partition. If this bit is cleared, a CF9h write of 6h or Eh will only reset the Host partition. It is recommended that BIOS should set this bit early on in the boot sequence, and then clear it and set the CF9LOCK bit prior to loading the OS. When this bit is set, the hardware assumes that bit 18 (CF9h Without Resume Well Reset Enable) is cleared. This register is locked by the CF9 Lockdown (CF9LOCK) bit. This register is not reset by a CF9h reset. reset_type=RSMRST_B
19	0x0 RO	**reserved (reserved1):** Reserved.
18	0x0 RW	**CF9h Without Resume Well Reset Enable (CWORWRE) (cworwre):** When this bit is set, a CF9h write of 6h or Eh will not cause internal Resume Well Reset (WrsmrstB) to be asserted and thus resume well logic will maintain its state. When this bit is cleared, CF9h write of 6h or Eh will also reset resume well logic. This bit is to be used when a second reset through CF9 write is desired upon power up or after resume from low power states. This bit has to be set prior to the write to CF9 register and has to be cleared upon completing the reset. Failing to do so prevents resume well registers from being reset in the future CF9 writes. reset_type=RSMRST_B
17:16	0x3 RW	**MAX_S0IX (MAX_S0IX (max_s0ix):** Indicated the maximum S0i state SOC can go

10.3.4 RST_CNT: Reset Control Register (RST_CNT)—Offset CF9h

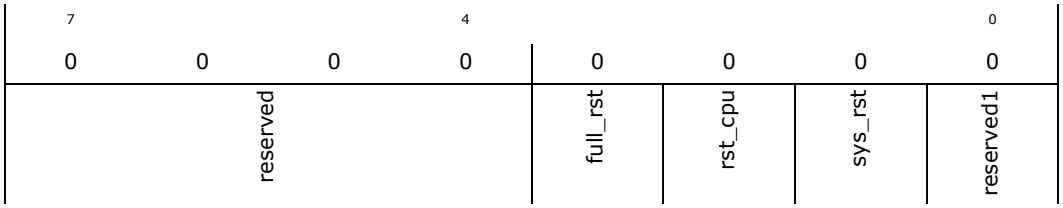
Reset Control Register

Access Method

Type: I/O Register
(Size: 8 bits)

Offset: CF9h

Default: 00h



Bit Range	Default & Access	Field Name (ID): Description
7:4	0x0 RO	**reserved:** Reserved.
3	0x0 RW	**Full Reset (FULL_RST) (full_rst):** When this bit is set to 1 and bit 1 is set to 1 (indicating Hard Reset, not Soft Reset), and the RST_CPU bit (bit 2) is written from 0 to 1, the PMC will do a full reset, including driving PMU_SLP_S3_B and PMU_SLP_S4_B active (low) for at least 3 (and no more than 6) seconds. When this bit is set, it also causes the full power cycle (PMU_SLP_S3/4_B assertion) in response to PMU_RESETBUTTON_B, COREPWROK, and Watchdog timer reset sources.
2	0x0 RW	**Reset CPU (RST_CPU) (rst_cpu):** This bit will cause either a hard or soft reset to the CPU depending on the state of the SYS_RST bit (bit 1 in this same register). The software will cause the reset by setting bit 2 from a 0 to a 1.

Bit Range	Default & Access	Field Name (ID): Description
1	0x0 RW	**System Reset (SYS_RST) (sys_rst):** This bit determines the type of reset caused via RST_CPU (bit 2 of this register). If SYS_RST is 0 when RST_CPU goes from 0 to 1, then the PMC will force INIT# active for 16 PCI clocks. If SYS_RST is 1 when RST_CPU goes from 0 to 1, then the PMC will force PCI reset active for about 1 ms, however the PMU_SLP_S3_B and PMU_SLP_S4_B signals assertion is dependent on the value of the FULL_RST (bit3 of this register).

Bit Range	Default & Access	Field Name (ID): Description
30	0x0 RW	**RCOMP Calibration Start (RcalStart):** When set to 1 this bit triggers the RCOMP FSM to start hunting for the correct values for strength and slew. This bit should be cleared after calibration has finished. Before setting the RcalStart bit RFSMEn must have been asserted for at least 5 clock cycles. The first calibration takes 10us to complete and subsequent calibrations take 3us. Details of this process are in the CFIP RCOMP Aspec.
29	0x0 RW	**RCOMP FSM Binary Chicken Bit (chicken_bit):** Toggling this bit Simulates a V1P8 Mode change. This will allow Binary re-calibration

25:24	0x0 RW	**IRCCLK Frequency Select (ircfreq_select):** Clock ircclk frequency. This signals indicate what frequency ircclk is. This is used for 1ms and 10ms counters. 00 if clk input is 25MHz (default, and SoC Clock) 01 if 50MHz 10 if 100MHz 11 if 125MHz
23:22	0x2 RW	**IRC Internal Clock Period (ircintclkperiod):** To select rcomp clock period. This is the compensation clock frequency/period. Clock is derived from ircclk (which can be 25MHz, 50MHz, 100MHz or 125MHz user must set ircfreq_select[1:0] accordingly) 00 40ns (64ns for ircclk=125MHz) 01 80ns (96ns for ircclk=125MHz) 10 120ns (128ns for ircclk=125MHz) (default) 11 160ns (192ns for ircclk=125MHz)
21:20	0x1 RW	**RCOMP FSM Stop Condition (RFSMStop):** RCOMP FSM Stop calibration condition. RCOMP FSM (pullup and pulldown) will finish calibrating once orcpupen/orcpdnen toggles. The toggling indicates the compensation value has been reached. This option is programmable for toggle once (single edge), toggle twice (double edge), toggle thrice (triple edge) or forcing it to finish after a certain cycle (defined by RFSMStopCyc). 00b = single edge detect (10 or 01) 01b = double egde detect (101 or 010) (default) 10b = triple edge detect (1010 or 0101) 11b = stop after x cycles (depending on ircstpcyc[3:0] value -- This is meant for debug)
19:16	0x4 RW	**RCOMP FSM Stop Cycles (RFSMStopCyc):** Number of cycles to stop RCOMP FSM from searching for strength and slew settings. Type: Message Bus Register (Size: 32 bits)

Offset: [Port: 0x13] + 1080h

Op Codes:
h - Read, h - Write

Bit Range	Default and Access	Field Name (ID): Description
31	0x0 RW	**RCOMP FSM Enable (RFSMEn):** 0 = state machine disabled (clock gated) 1 = state machine enabled It is important to have this bit enabled in order for all internal clocks inside the RCOMP FSM to run.
30	0x0 RW	**RCOMP Calibration Start (RcalStart):** When set to 1 this bit triggers the RCOMP FSM to start hunting for the correct values for strength and slew. This bit should be cleared after calibration has finished. Before setting the RcalStart bit RFSMEn must have been asserted for at least 5 clock cycles. The first calibration takes 10us to complete and subsequent calibrations take 3us. Details of this process are in the CFIP RCOMP A Specification
29	0x0 RW	**RCOMP FSM Binary Chicken Bit (chicken_bit):** Toggling this bit Simulates a V1P8 Mode change. This will allow Binary re-calibration
28:26	0x0 RW	**reserved:** reserved
25:24	0x0 RW	**IRCCLK Frequency Select (ircfreq_select):** Clock ircclk frequency. This signals indicate what frequency ircclk is. This is used for 1 ms and 10 ms counters. 00 if clk input is 25 MHz (default, and SoC Clock) 01 if 50 MHz 10 if 100 MHz 11 if 125 MHz
23:22	0x3 RW	**IRC Internal Clock Period (ircintclkperiod):** To select rcomp clock period. This is the compensation clock frequency/period. Clock is derived from ircclk (which can be 25 MHz, 50 MHz, 100 MHz or 125 MHz user must set ircfreq_select[1:0] accordingly) 00 40 ns (64 ns for ircclk=125 MHz) 01 80 ns (96 ns for ircclk=125 MHz) 10 120 ns (128 ns for ircclk=125 MHz) (default) 11 160 ns (192 ns for ircclk=125 MHz)

Bit Range	Default and Access	Field Name (ID): Description
21:20	0x1 RW	**RCOMP FSM Stop Condition (RFSMStop):** RCOMP FSM Stop calibration condition. RCOMP FSM (Pull-up and Pull-down) will finish calibrating once orcpupen/orcpdnen toggles. The toggling indicates the compensation value has been reached. This option is programmable for toggle once (single edge), toggle twice (double edge), toggle thrice (triple edge) or forcing it to finish after a certain cycle (defined by RFSMStopCyc). 00b = single edge detect (10 or 01) 01b = double edge detect (101 or 010) (default) 10b = triple edge detect (1010 or 0101) 11b = stop after x cycles (depending on ircstpcyc[3:0] value -- This is meant for debug)
19:16	0x4 RW	**RCOMP FSM Stop Cycles (RFSMStopCyc):** Number of cycles to stop RCOMP FSM from searching for strength and slew settings. RFSMStop must be set to 11b for this option to take affect. 0000b = 0 cycle (illegal option) 0001b = 1 cycle (illegal option) 0010b = 2 cycles (illegal option) 0011b = 3 cycles (illegal option) 0100b = 4 cycles ... 1110b = 14 cycles 1111b = 15 cycles (maximum allowed) This is meant for debug.
15:8	0x1d RW	**Initial Pull-up Value (InitCalValP):** Initial pleg calibration value. RCOMP FSM will always start with this values for Pull-up calibration.
7:0	0x1d RW	**Initial Pull-down Value (InitCalValN):** Initial nleg calibration value. RCOMP FSM will always start with this values for Pull-down calibration.

Bit Range	Default and Access	Field Name (ID): Description
16	0x0 RW	**Analog Mux Enable (analogmuxen):** Enables the analog mux at the Pad SIP
15:12	0x0 RW	**I/O Standby State (IOSState):** The I/O Standby State defines which state the pin should be parked in when the I/O is in a standby state. 0 = Latch last value driven on TX, TX Enable and RX Enable 1 = Drive 0 with RX disabled 2 = Drive 1 with RX disabled 3 = Drive 0 with RX enabled 4 = Drive 1 with RX enabled 5 = Hi-Z 6 = TX Disabled and RX Enabled (that is, wake or interrupt) Others = Reserved
11:10	0x0 RW	**I/O Standby Termination (IOSTerm):** IOSTerm defines the behavior of the termination logic when the I/O Standby state has been triggered. The value of the termination is determined in Term[2:0]. 0 = Same as state specified in Term. 1 = Disable Pull-up and Pull-down 2 = Enable Pull-down 3 = Enable Pull-up
9:8	0x0 RW	**reserved5:** Reserved.
7:4	0x0 RW	**Invert Rx Tx (InvRXTX):** These bits invert the RX/TX Data and RX/TX Enables to the CFIO buffer. Typically this is used to indicate an active high or low signal. This setting affects all modes. 0 = No Inversion 1 = Inversion Enabled [0] RX Enable [1] TX Enable [2] RX Data [3] TX Data **Note:** If GPIOEn=1, InvRxTx must be 0x0, and while GPIOEn=0 InvRxTX can either be 0x0 or 0x2 depending on function selected.
3	0x0 RW	**Open Drain Enable (ODEn):** Open Drain Enable muxes TX Data to output 0 and TX Enable is connected to TX Data. This allows only zero to be driven on the output buffer and ones are pulled up with either an external or internal Pull-up. 0 = Disabled 1 = Enabled
2:0	0x0 RW	**Interrupt and Wake Configuration (IntWakeCfg):** Configure the edge detection logic that is used to trigger interrupts and wakes. Pad must be configured as an input. For active low level interrupts then invert the RX Data (that is, InvRXTX). 0 = Interrupt/Wake Disable (Disabled and no Pad State toggles trigger the Wake/Interrupt logic) 1 = Falling Edge Detect Interrupt/Wake 2 = Rising Edge Detect Interrupt/Wake 3 = Falling or Rising Edge Detect Interrupt/Wake 4 = Level Interrupt/Wake (Bypass edge detect logic and Pad state is directly toggling the Wake/Interrupt logic) Others = Reserved
